Real-world sensing

Evolution of Sensing Technologies for Realizing Precise Digital Twins

Digital twins which enable various simulations are essential for the total optimization of social systems. Sensing technologies to reproduce the real-world in cyberspace are important.

Technologies to deeply understand meaning with ① various sensors and ② AI analysis
③ Technologies to reduce the cost of AI construction needed for deep understanding

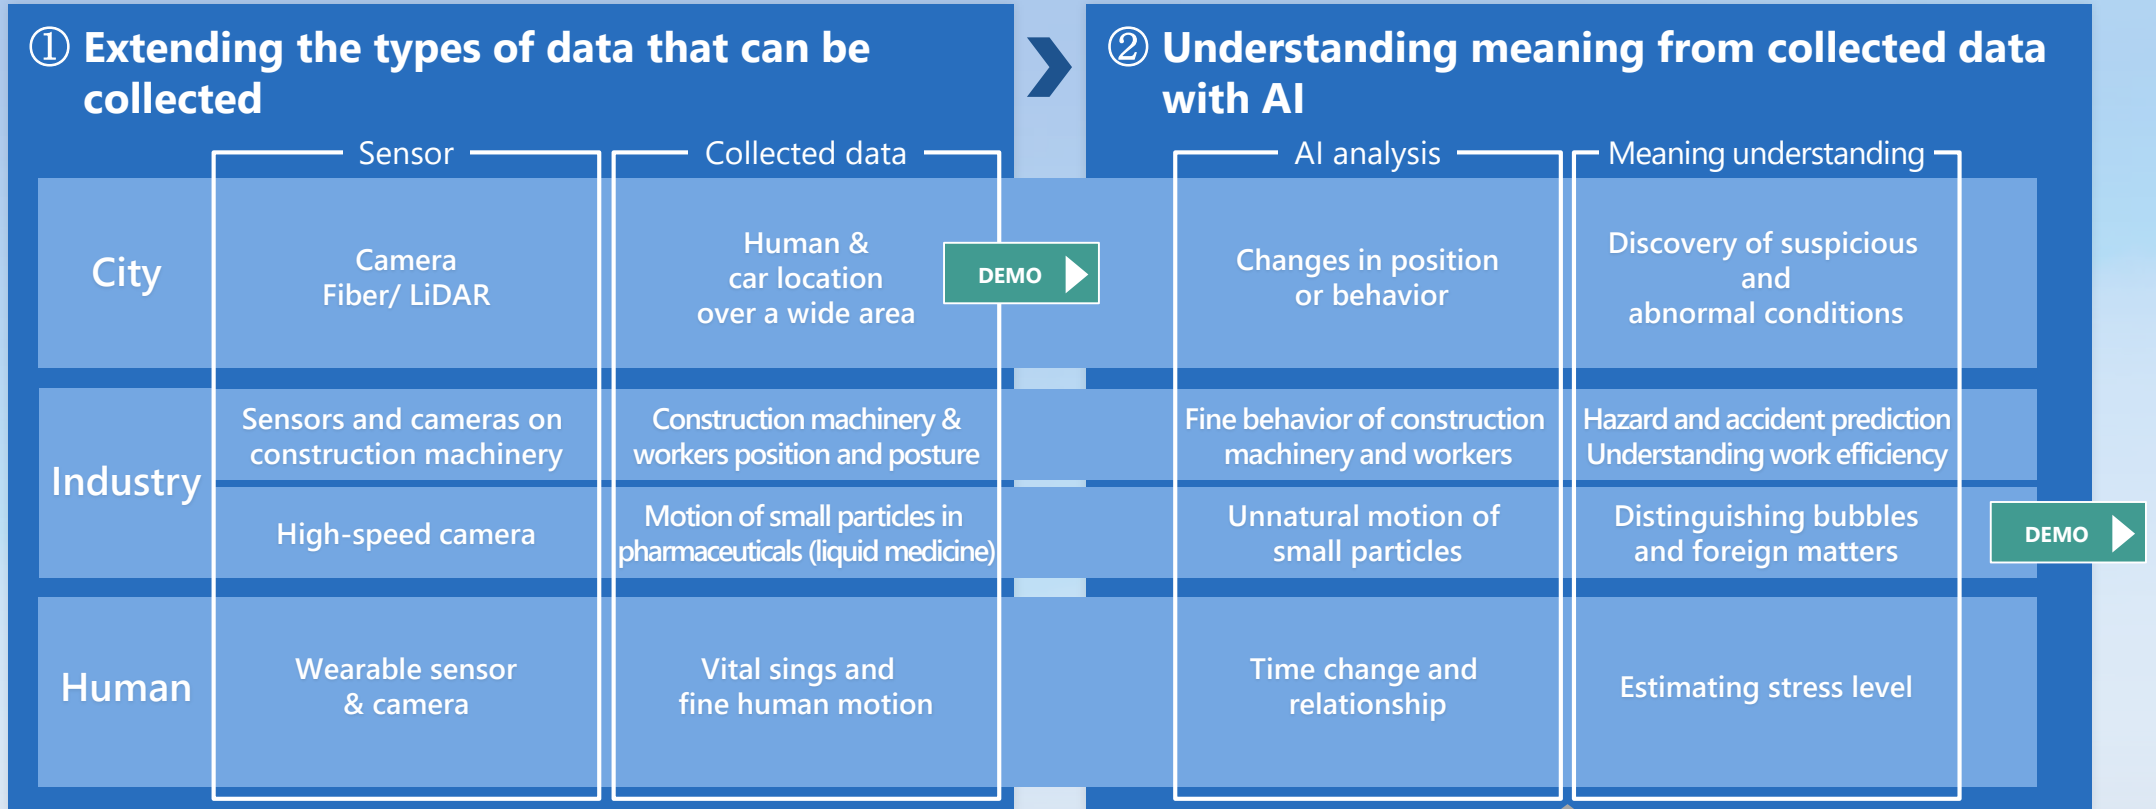

Real-world

① Extending the types of data that can be collected

② Understanding meaning from collected data with AI

③ Cost reduction of AI construction (training data collection, training methods, annotation)

DEMO

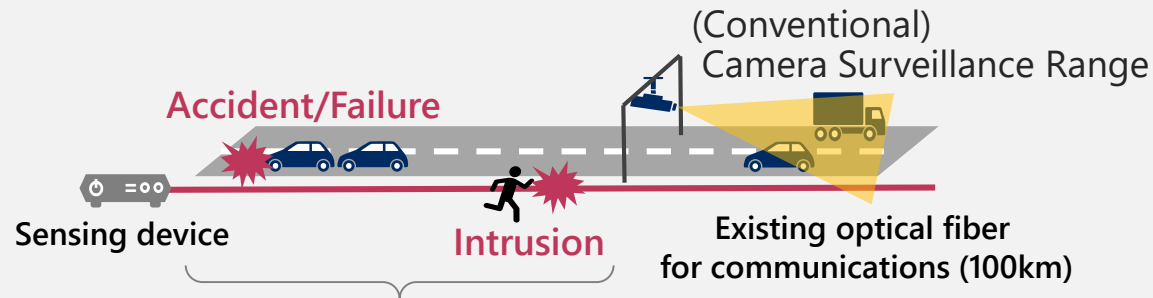

Precise understanding of the position and condition of people and objects over a wide area with existing optical fiber for communications

Sense vibration distributions over a wide area (up to 380 km*, 10 times longer than the competitors') at once by making full use of advanced optical communication technology

*By two-way communication systems

Joint demonstration with Verizon and Central Nippon Expressway Company Limited

Real-time monitoring of wide-area anomalies through continuous monitoring of the entire line with no monitoring leakage
Smooth traffic control through immediate response

Unmonitored area (~several tens of km in rural areas) can be monitored using existing fiber-optic cables

Real-time detection of intrusion and moving objects using outdoor optical fiber cable
Optical fiber cables installed along railway track detect running train and intruders

Demonstration overview

Intrusion detection

Detect people approaching the track with underground optical fibers

Train detection

Monitor railway traffic (presence and direction)

GUI

Railway Traffic monitoring (moving icon)

Musashi Kosugi ← → Mukaigawara

Intrusion detection (Alarm with intrusion position)

Intruder alarm

Sensing data

Detect foreign matters from their motion trajectory pattern in liquid pharmaceuticals

The AI classifies fine particles into foreign matters and bubbles from their motion trajectory pattern on high-speed camera videos. This technology enables a rapid increase in production for liquid products and realizes high inspection reliability.

Imaging

Shake the bottle

Floating bubbles and foreign matters

Tracking

Track all particles

Trajectories from over 100 fps video

Classification

Classify all particles into bubbles and foreign matters

Characteristic motion

By daring to shake the bottle filled with liquid, the difference of motion between foreign particles and minute bubbles becomes clear and they can be classified correctly. It enables to reduce over-detection

Real-world sensing

Easy registration of new products in an image recognition just by turning it in front of a camera

Dramatically reduce human and time costs of new product registration work which is required for product management using image recognition.

BEFORE

Manual editing work such as image cropping is needed for registration. It requires 30 minutes per product.

AFTER

Registration is completed in just 10 to 20 seconds just by holding and turning a new product in front of a camera.

- No specialized shooting equipment required
- Automatic editing with AI technology

Cropping of product area

Removal of unnecessary images

\Orchestrating a brighter world
