

**EXPRESSCLUSTER X 4.3 for Linux  
Reference Guide**

*Release 5*

**NEC Corporation**

**Apr 26, 2024**

## TABLE OF CONTENTS:

<b>1</b>	<b>Preface</b>	<b>1</b>
1.1	Who Should Use This Guide . . . . .	1
1.2	How This Guide is Organized . . . . .	2
1.3	EXPRESSCLUSTER Documentation Set . . . . .	3
1.4	Conventions . . . . .	4
1.5	Contacting NEC . . . . .	5
<b>2</b>	<b>Parameter details</b>	<b>7</b>
2.1	Parameter settings . . . . .	8
2.2	Cluster properties . . . . .	9
2.3	Server Common Properties . . . . .	71
2.4	Server properties . . . . .	74
2.5	Group Properties . . . . .	82
2.6	Group Resource Properties . . . . .	83
2.7	Monitor Resource Properties . . . . .	84
2.8	Parameters list . . . . .	85
2.9	Upper limits of registration . . . . .	140
<b>3</b>	<b>Group resource details</b>	<b>141</b>
3.1	Group resources and supported EXPRESSCLUSTER versions . . . . .	142
3.2	Attributes common to group resources . . . . .	143
3.3	Group common properties . . . . .	180
3.4	Group properties . . . . .	183
3.5	Resource Properties . . . . .	194
3.6	Understanding EXEC resources . . . . .	205
3.7	Understanding Disk resource . . . . .	248
3.8	Understanding Floating IP resource . . . . .	258
3.9	Understanding Virtual IP resources . . . . .	271
3.10	Understanding Mirror disk resources . . . . .	284
3.11	Understanding Hybrid disk resources . . . . .	326
3.12	Understanding NAS resource . . . . .	341
3.13	Understanding Volume manager resources . . . . .	347
3.14	Understanding VM resources . . . . .	360
3.15	Understanding Dynamic DNS resources . . . . .	367
3.16	Understanding AWS Elastic IP resources . . . . .	374
3.17	Understanding AWS Virtual IP resources . . . . .	378
3.18	Understanding AWS DNS resources . . . . .	383
3.19	Understanding Azure probe port resources . . . . .	387
3.20	Understanding Azure DNS resources . . . . .	391
3.21	Understanding Google Cloud Virtual IP resources . . . . .	395

3.22	Understanding Google Cloud DNS resources . . . . .	399
3.23	Understanding Oracle Cloud Virtual IP resources . . . . .	402
<b>4</b>	<b>Monitor resource details</b>	<b>405</b>
4.1	Monitor resource . . . . .	407
4.2	Monitor Common Properties . . . . .	485
4.3	Monitor resource properties . . . . .	486
4.4	Understanding the disk monitor resources . . . . .	496
4.5	Understanding IP monitor resources . . . . .	504
4.6	Understanding floating IP monitor resources . . . . .	507
4.7	Understanding NIC Link Up/Down monitor resources . . . . .	508
4.8	Understanding mirror disk connect monitor resources . . . . .	511
4.9	Understanding mirror disk monitor resources . . . . .	512
4.10	Understanding hybrid disk connect monitor resources . . . . .	513
4.11	Understanding hybrid disk monitor resources . . . . .	514
4.12	Understanding PID monitor resources . . . . .	515
4.13	Understanding User mode monitor resources . . . . .	516
4.14	Understanding multi target monitor resources . . . . .	523
4.15	Understanding virtual IP monitor resources . . . . .	527
4.16	Understanding ARP monitor resources . . . . .	528
4.17	Understanding custom monitor resources . . . . .	529
4.18	Understanding volume manager monitor resources . . . . .	532
4.19	Understanding message receive monitor resources . . . . .	534
4.20	Understanding VM monitor resources . . . . .	539
4.21	Understanding Dynamic DNS monitor resources . . . . .	541
4.22	Understanding process name monitor resources . . . . .	542
4.23	Understanding BMC monitor resources . . . . .	544
4.24	Understanding DB2 monitor resources . . . . .	545
4.25	Understanding FTP monitor resources . . . . .	549
4.26	Understanding HTTP monitor resources . . . . .	551
4.27	Understanding IMAP4 monitor resources . . . . .	553
4.28	Understanding MySQL monitor resources . . . . .	555
4.29	Understanding NFS monitor resources . . . . .	559
4.30	Understanding ODBC monitor resources . . . . .	561
4.31	Understanding Oracle monitor resources . . . . .	564
4.32	Understanding Oracle Clusterware Synchronization Management monitor resources . . . . .	571
4.33	Understanding POP3 monitor resources . . . . .	572
4.34	Understanding PostgreSQL monitor resources . . . . .	574
4.35	Understanding Samba monitor resources . . . . .	578
4.36	Understanding SMTP monitor resources . . . . .	580
4.37	Understanding SQL Server monitor resources . . . . .	581
4.38	Understanding Sybase monitor resources . . . . .	585
4.39	Understanding Tuxedo monitor resources . . . . .	589
4.40	Understanding WebLogic monitor resources . . . . .	590
4.41	Understanding WebSphere monitor resources . . . . .	594
4.42	Understanding WebOTX monitor resources . . . . .	596
4.43	Understanding JVM monitor resources . . . . .	598
4.44	Understanding System monitor resources . . . . .	648
4.45	Understanding Process resource monitor resources . . . . .	660
4.46	Understanding AWS Elastic IP monitor resources . . . . .	667
4.47	Understanding AWS Virtual IP monitor resources . . . . .	668
4.48	Understanding AWS AZ monitor resources . . . . .	669
4.49	Understanding AWS DNS probe monitor resources . . . . .	670
4.50	Understanding Azure probe port monitor resources . . . . .	672

4.51	Understanding Azure load balance monitor resources . . . . .	673
4.52	Understanding Azure DNS monitor resources . . . . .	674
4.53	Understanding Google Cloud Virtual IP monitor resources . . . . .	675
4.54	Understanding Google Cloud load balance monitor resources . . . . .	676
4.55	Understanding Google Cloud DNS monitor resources . . . . .	677
4.56	Understanding Oracle Cloud Virtual IP monitor resources . . . . .	678
4.57	Understanding Oracle Cloud load balance monitor resources . . . . .	679
<b>5</b>	<b>Heartbeat resources details</b>	<b>681</b>
5.1	What are heartbeat resources? . . . . .	682
5.2	Understanding LAN heartbeat resources . . . . .	686
5.3	Understanding kernel mode LAN heartbeat resources . . . . .	687
5.4	Understanding disk heartbeat resources . . . . .	688
5.5	Understanding COM heartbeat resources . . . . .	692

7.4	Script for forced stop . . . . .	716
7.5	Chassis Identify . . . . .	718
7.6	Alert Service . . . . .	721
7.7	SNMP linkage . . . . .	724
7.8	Cluster service automatic startup prohibition after improper stop . . . . .	730
7.9	Grace period dependence at the automatic failover between server groups . . . . .	731
7.10	Witness server service . . . . .	732
<b>8</b>	<b>EXPRESSCLUSTER command reference</b>	<b>737</b>
8.1	Operating the cluster from the command line . . . . .	739
8.2	EXPRESSCLUSTER commands . . . . .	740
8.3	Displaying the cluster status (clpstat command) . . . . .	743
8.4	Operating the cluster (clpcl command) . . . . .	761
8.5	Shutting down a specified server (clpdown command) . . . . .	765
8.6	Shutting down the entire cluster (clpstdn command) . . . . .	766
8.7	Operating groups (clpgrp command) . . . . .	767
8.8	Collecting logs (clplogcc command) . . . . .	775
8.9	Changing, backing up, and checking cluster configuration data (clpcfctrl command) . . . . .	784
8.10	Adjusting time-out temporarily (clptoratio command) . . . . .	803
8.11	Modifying the log level and size (clplogcf command) . . . . .	806
8.12	Managing licenses (clplnsc command) . . . . .	813
8.13	Locking disk I/O (clproset command) . . . . .	819
8.14	Mirror-disk-related commands . . . . .	821
8.15	Hybrid-disk-related commands . . . . .	860
8.16	Outputting messages (clplogcmd command) . . . . .	891
8.17	Controlling monitor resources (clpmonctrl command) . . . . .	893
8.18	Controlling group resources (clprsc command) . . . . .	898

8.19	Controlling reboot count (clpregctrl command)	902
8.20	Turning off warning light (clplamp command)	904
8.21	Controlling CPU frequency (clpcpufreq command)	905
8.22	Controlling chassis identify lamp (clpledctrl command)	908
8.23	Processing inter-cluster linkage (clptrnreq command)	910
8.24	Requesting processing to cluster servers (clprexec command)	912
8.25	Changing BMC information (clpbmccnf command)	916
8.26	Controlling cluster activation synchronization wait processing (clpbwctrl command)	918
8.27	Estimating the amount of resource usage (clpprer command)	920
8.28	Checking the process health (clphealthchk command)	925
8.29	Controlling the rest point of DB2 (clpdb2still command)	927
8.30	Controlling the rest point of MySQL (clpmysqlstill command)	929
8.31	Controlling the rest point of Oracle (clporclstill command)	931
8.32	Controlling the rest point of PostgreSQL (clppsqlstill command)	933
8.33	Controlling the rest point of SQL Server (clpmssqlstill command)	935
8.34	Controlling the rest point of Sybase (clpsybasestill command)	938
8.35	Displaying the cluster statistics information (clpperfc command)	940
8.36	Checking the cluster configuration information (clpcfchk command)	942
8.37	Creating a cluster configuration data file (clpcfset command)	944
8.38	Performing encryption (clpencrypt command)	1048
<b>9</b>	<b>Troubleshooting</b>	<b>1049</b>
9.1	Troubleshooting	1050
9.2	Troubleshooting problems with VERITAS volume manager	1083
9.3	To confirm the progress of the fsck / xfs_repair command	1086
<b>10</b>	<b>Error messages</b>	<b>1087</b>
10.1	Messages	1088
10.2	Messages reported by syslog, alert, mail, SNMP trap, and Message Topic	1089
10.3	Driver syslog messages	1190
10.4	Detailed information in activating and deactivating group resources	1229
10.5	Detailed info of monitor resource errors	1247
10.6	JVM monitor resource log output messages	1280
<b>11</b>	<b>Glossary</b>	<b>1305</b>

**PREFACE**

## **1.1 Who Should Use This Guide**

The *EXPRESSCLUSTER X Reference Guide* is intended for system administrators. Detailed information for setting up a cluster system, function of the product, and how to troubleshoot the problems are covered in this guide. The guide provides supplemental information to the *Installation and Configuration Guide*.

## 1.2 How This Guide is Organized

- *2. Parameter details:* Provides information on parameters configured in EXPRESSCLUSTER.
- *3. Group resource details:* Provides information on group resource which configures a failover group.
- *4. Monitor resource details:* Provides information on monitor resource which works as a monitoring unit in EXPRESSCLUSTER.
- *5. Heartbeat resources details:* Provides information on heartbeat resource.
- *6. Network partition resolution resources details:* Provides information on the network partition resolution resource.
- *7. Information on other settings:* Provides information on other configurations.
- *8. EXPRESSCLUSTER command reference:* Provides information on commands available to use in EXPRESS-CLUSTER.
- *9. Troubleshooting:* Provides instruction on how to troubleshoot the problem.
- *10. Error messages:* Provides explanation on error messages displayed during EXPRESSCLUSTER operation.
- *11. Glossary*

## 1.3 EXPRESSCLUSTER Documentation Set

The EXPRESSCLUSTER manuals consist of the following four guides. The title and purpose of each guide is described below.

### EXPRESSCLUSTER X Getting Started Guide

This guide is intended for all users. The guide covers topics such as product overview, system requirements, and known problems.

### EXPRESSCLUSTER X Installation and Configuration Guide

This guide is intended for system engineers and administrators who want to build, operate, and maintain a cluster system. Instructions for designing, installing, and configuring a cluster system with EXPRESSCLUSTER are covered in this guide.

### EXPRESSCLUSTER X Reference Guide

This guide is intended for system administrators. The guide covers topics such as how to operate EXPRESSCLUSTER, function of each module and troubleshooting. The guide is complement to the *Installation and Configuration Guide*.

### EXPRESSCLUSTER X Maintenance Guide

This guide is intended for administrators and for system administrators who want to build, operate, and maintain EXPRESSCLUSTER-based cluster systems. The guide describes maintenance-related topics for EXPRESSCLUSTER.

### EXPRESSCLUSTER X Hardware Feature Guide

This guide is intended for administrators and for system engineers who want to build EXPRESSCLUSTER-based cluster systems. The guide describes features to work with specific hardware, serving as a supplement to the Installation and Configuration Guide.

### EXPRESSCLUSTER X Legacy Feature Guide

This guide is intended for administrators and for system engineers who want to build EXPRESSCLUSTER-based cluster systems. The guide describes EXPRESSCLUSTER X 4.0 WebManager, Builder, and EXPRESSCLUSTER Ver 8.0 compatible commands.

## 1.4 Conventions

In this guide, **Note**, **Important**, **Related Information** are used as follows:

---

**Note:** Used when the information given is important, but not related to the data loss and damage to the system and machine.

---

---

**Important:** Used when the information given is necessary to avoid the data loss and damage to the system and machine.

---

**See also:**

Used to describe the location of the information given at the reference destination.

The following conventions are used in this guide.

Convention	Usage	Example
<b>Bold</b>	Indicates graphical objects, such as fields, list boxes, menu selections, buttons, labels, icons, etc.	In <b>User Name</b> , type your name. On the <b>File</b> menu, click <b>Open Database</b> .
Angled bracket within the command line	Indicates that the value specified inside of the angled bracket can be omitted.	<code>clpstat -s [-h <i>host_name</i>]</code>
Monospace	Indicates path names, commands, system output (message, prompt, etc.), directory, file names, functions and parameters.	<code>c:\Program files\EXPRESSCLUSTER</code>
<b>bold</b>	Indicates the value that a user actually enters from a command line.	Enter the following: <b>clpcl -s -a</b>
<i>italic</i>	Indicates that users should replace italicized part with values that they are actually working with.	<code>clpstat -s [-h <i>host_name</i>]</code>

In the figures of this guide, this icon represents EXPRESSCLUSTER.

## **1.5 Contacting NEC**

For the latest product information, visit our website below:

<https://www.nec.com/global/prod/expresscluster/>

## **PARAMETER DETAILS**

This chapter describes the details of the parameters configured in EXPRESSCLUSTER.

This chapter covers:

- *2.1. Parameter settings*
- *2.2. Cluster properties*
- *2.3. Server Common Properties*
- *2.4. Server properties*
- *2.5. Group Properties*
- *2.6. Group Resource Properties*
- *2.7. Monitor Resource Properties*
- *2.8. Parameters list*
- *2.9. Upper limits of registration*

## **2.1 Parameter settings**

This section describes the details of the parameters configured in EXPRESSCLUSTER.

Use Cluster WebUI to configure the parameters.

For more information of Cluster WebUI, refer to the online manual of Cluster WebUI.

## 2.2 Cluster properties

In **Cluster Properties**, you can view and change the cluster's settings.

### 2.2.1 Info tab

You can view the cluster name, and enter or change a comment for this cluster.

The screenshot shows a window titled "Cluster Properties | cluster" with a close button (X) in the top right corner. Below the title bar is a tabbed interface with the "Info" tab selected. Other tabs include "Interconnect", "NP Resolution", "Timeout", "Port No.", "Port No.(Mirror)", "Port No.(Log)", "Monitor", "Recovery", "Alert Service", "WebManager", "Alert Log", "Delay Warning", "Mirror Agent", "Mirror Driver", "JVM Monitor", and "Extension". The "Info" tab contains three fields: "Cluster Name" with a text box containing "cluster", "Comment" with an empty text box, and "Language" with a dropdown menu showing "English". At the bottom right are three buttons: "OK", "Cancel", and "Apply".

#### Cluster Name

The cluster name is displayed. You cannot change the name here.

#### Comment (Within 127 bytes)

You can enter a comment for the cluster. Only alphanumeric characters are allowed.

#### Language

Select a language for cluster from the following. Set the language (locale) of OS on which the Cluster WebUI runs.

- English
- Japanese
- Chinese

Cluster WebUI and the results of clpstat command are displayed in the language set in the **Language** settings on the cluster properties.

---

**Note:** Run the clpstat command in the environment where the font of the specified language can be displayed. On the console which is connected to a server directly, setting a frame buffer is required. When logging on to the server remotely using ssh, a terminal emulator which can display the specified language may be needed.

---

## 2.2.2 Interconnect tab

This tab allows you to set up network communication paths between cluster servers.

Cluster Properties | cluster ✕

[Info](#)
[Interconnect](#)
[NP Resolution](#)
[Timeout](#)
[Port No.](#)
[Port No.\(Mirror\)](#)
[Port No.\(Log\)](#)

[Extension](#)

Heartbeat I/F Priority List

Priority	Type	MDC	server1	server2
1	Kernel Mode	Do Not Use	192.168.0.1	192.168.0.2
2	Kernel Mode	Do Not Use	10.0.0.1	10.0.0.2
3	DISK	Do Not Use	/dev/sdb1	/dev/sdb1
4	COM	Do Not Use	/dev/ttyS0	/dev/ttyS0
5	Witness	Do Not Use	Use	Use

Server Down Notification ☒

The **Communication paths between servers list** displays network communication paths between servers in the cluster.

### Add

Adds a communication path. To specify the IP address of the communication path for each server, click a cell in each server's column, and then select or enter the address. If some servers are not connected on the communication path, leave the cells for all the unconnected servers empty.

### Remove

Removes a communication path. Select the column of the communication path to remove, and then click **Remove** to remove the selected path.

### Properties

Displays heartbeat properties window. This is only available only when the type is DISK or Witness.

### DISK HeartBeat Properties

Displays DISK heartbeat properties.

Disk HeartBeat Properties		
Server	Device	Raw Device
server1	/dev/sdb1	/dev/raw/raw1
server2	/dev/sdb1	/dev/raw/raw1

OK Cancel

#### Server

Displays server list.

#### Device

Displays the device configured in the previous window.

#### Raw Device

When using RAW device, set RAW device by selecting or entering directly.

When not using RAW device, set blank.

#### Witness heartbeat properties

Witness HeartBeat Properties	
Target Host*	
Service Port*	80
HTTP Timeout*	10 sec
Use SSL	<input type="checkbox"/>
Initialize	
OK Cancel	

#### Target host

Sets the host address of the Witness server to be connected.

#### Service port

Sets the port number of the Witness server to be connected.

### Use SSL

Configures whether or not to use SSL for communicating with the Witness server. When the checkbox is selected, SSL is used, and when the checkbox is not selected, it is not used.

Use OpenSSL 1.0/1.1 for SSL. By default, the following libraries are used:

- libssl.so.10 (if you installed the rpm package of EXPRESSCLUSTER)
- libssl.so.1.0.0 (if you installed the deb package of EXPRESSCLUSTER)

To use other libraries, go to the **Encryption** tab and set **SSL Library** and **Crypto Library**.

### Use Proxy

Configures whether or not to use a proxy for communicating with the Witness server. When the checkbox is selected, the settings of the **Proxy** tab in the server properties become effective. When the checkbox is not selected, any proxy setting is not used even if the proxy is set in the server properties.

### HTTP Timeout

Sets the timeout of receiving HTTP response.

### Initialize

Resets the Witness heartbeat properties settings to default values.

### Priority

When multiple interconnects are configured, the communication path with the smallest number in the **Priority** column is used preferentially for the internal communication among cluster servers. To change the priority, change the order of selected rows with the arrows.

It is recommended to specify a higher priority for the interconnect communication path than any other paths.

---

**Note:** **Priority** is used to decide on the priority of communication routes used for internal communication between the servers in the cluster. Heartbeat between the servers in the cluster is implemented on all communication routes that are set up for heartbeat, regardless of **Priority**.

---

### Type

Select the path to be used for heartbeat from **Kernel Mode**, **User Mode**, **DISK**, **COM**, **BMC**, **Witness**, or **Mirror Communication Only**

- **Kernel mode** performs alive monitoring by using kernel mode LAN heartbeat resources.
- **User Mode** performs alive monitoring by using LAN heartbeat resources.
- **DISK** performs alive monitoring by using disk heartbeat resources.
- **COM** performs alive monitoring by using COM heartbeat resources.
- **BMC** performs alive monitoring by using BMC heartbeat resources.
- **Witness** performs alive monitoring by using Witness heartbeat resources.

For details about the heartbeat resources, see "[5. Heartbeat resources details](#)" in this guide.

### MDC

To use a communication path as the mirror disk connect, click **MDC** and then select **Mirror Connect Disk**.

The contents to be entered differ by type.

- **Kernel Mode, User Mode, Mirror Communication Only**

Select **Mirror Disk Connect** from the combo box.

When the mirror disk connect is not used, select **Do Not Use**.

---

**Note:** A combination of IPv4 and IPv6 is not allowed for the IP addresses that are used for mirror disk connects. Specify IP addresses in either IPv4 only or IPv6 only for all mirror disk connects.

---

- **DISK, COM, BMC, Witness**

The mirror disk connect cannot be used.

**MDC** automatically changes to **Do Not Use** and can no longer be edited.

### Server column

Entry differs depending on the type.

- **Kernel Mode, User Mode, Mirror Communication Only**

Enter IP address. Set blank to the not used communication path.

- **DISK**

Enter disk device. Set blank when not using DISK device.

- **COM**

Enter COM device. Set blank when not using COM device.

- **BMC**

Enter the IP address of the BMC. Set blank when not using the BMC.

- **Witness**

Select **Use** or **Do Not Use**.

---

**Note:**

More than one IP addresses which belong to the same network address cannot exist in a single server.

And also, inclusive relation cannot exist like the following relation.

IP address:10.1.1.10, subnet mask:255.255.0.0

IP address:10.1.2.10, subnet mask:255.255.255.0

---

### Server down notification

When a server stops successfully (including a shutdown or reboot), the server is reported to be down to other servers in the cluster. You can perform failovers faster by reporting this in advance.

When there is a failure to deactivate groups when a server stops (including a shutdown or reboot), or when other abnormalities occur, other servers are not notified of the server that went down regardless of the server down notification settings.

- When Follow the default dependence is selected:

A server going down is reported.

- When Follow the default dependence is not selected:

A server going down is not reported.

---

**Note:** Do not use server down notification when using a hybrid disk resource.

---

Click **Detailed Settings** to configure the details of server reset notification.

---

**Note:**

Making the settings effective requires the following:  
The check box of server down notification is checked.  
Kernel mode LAN heartbeat resources are set.  
Using a kernel newly supported by internal version 4.3.0-1 or later.

---

**Detail Configuration of Server Down Notification**

Server Reset Notification ☐

Execute Server Alive Check ☐

Timeout  sec

Initialize

OK Cancel Apply

**Server Reset Notification**

This notification by the server means informing other servers of its stop due to **Keepalive Reset** or **Keepalive Panic**.

- If the check box is checked:  
With the notification, its source server is regarded as down.
- If the check box is not checked:  
No reaction happens even with the notification.

**Execute Server Alive Check**

- If the check box is checked:  
Whether the server is alive is checked before the failover.
- If the check box is not checked:  
Whether the server is alive is not checked before the failover.

**Timeout**

Specify a value for the timeout of checking whether the server is alive. If the value is larger than that for the heartbeat timeout, the latter timeout value is applied.

**Tuning**

Displays heartbeat I/F tuning property window.

**Heartbeat I/F Tuning Properties**

**Heartbeat I/F Tuning Properties**

**Open/Close Timing** ☒ Only at Start/Stop  
☐ Every Heartbeat Interval

**Bind Check** ☐ Enable  
☒ Disable

Initialize

OK Cancel Apply

- **Open/Close Timing**

- Only at Start/Stop  
Opens raw device when a cluster starts and close it when a cluster stops. Performs only reads and writes of raw device at each heartbeat interval.
- Every Heartbeat Interval  
Opens raw device when a cluster starts, and closes it when a cluster stops. Performs open, reads, writes and close of raw device at each heartbeat interval.

- **Bind Check**

- Enable  
Checks if raw device for disk heartbeat is not bound to the actual device other than for disk heartbeat. Binding raw device is not performed if it is bound to the actual device other than for disk heartbeat. When binding a disk is not performed, the status of disk heartbeat resource becomes offline.
- Disable  
Does not check if raw device for disk heartbeat is not bound to the actual device other than for disk heartbeat. If raw device is bound to the actual device other than for disk heartbeat, the bind is canceled and raw device is bound to the actual device for disk heartbeat.

## 2.2.3 NP Resolution tab

Change the setting of the network partition interface. The network partition resolution interface used for EXPRESS-CLUSTER is displayed on the **NP**.

Cluster Properties | cluster

### Add

Add network partition resolution I/F. Click the **Type** column cell and select the type of NP resolution (**Ping** or **HTTP**). If you select **Ping**, click the **Ping target** column cell and set the IP address. Click the cell of each server and set **Use** or **Do Not Use**.

### Remove

Remove network partition resolution I/F. Select network partition resolution I/F to be removed and click **Remove**, then the selected network partition resolution I/F is removed.

### Properties

Display the **Ping NP Properties** or the **HTTP NP Properties** window.

### Ping NP Properties

### Ping NP Properties

Cancel

- Add Group List
  - Add group.
  - The maximum number of registered group is 16.
  - If multiple IP addresses are registered in one group, and if the state in which no response to the Ping command is returned from all the IP addresses is maintained, NP resolution processing cannot be performed (if there is even one IP address responding to the Ping command, NP resolution processing can be performed). Also, if multiple groups are registered, and if the state in which no response to the Ping command is returned from any one group is maintained, NP resolution processing cannot be performed (if all groups respond to the Ping command, NP resolution processing can be done).
- Remove Group List
  - Remove the selected group.
- Add IP Address List
  - Add IP address to the selected group.
  - The maximum number of registered IP address is 16.
  - Maximum 256 IP addresses are able to be registered to a single Ping NP, and 16 kinds of IP addresses can be registered. (The same IP addresses can be used.)
- Remove IP Address List
  - Remove the selected IP address from the list.
- Edit
  - Edit the selected IP address.

- Interval
  - Set the Ping interval.
- Timeout
  - Set the Ping timeout.
- Retry Count
  - Set the retry count.
- Initialize
  - Set the interval, timeout and retry count to the default values. Note that, when an interval and retry count are specified, the following conditional expression must be satisfied.  
If not satisfied, NP resolution processing cannot be performed normally.

**Conditional expression) Heartbeat timeout**

**> (Ping NP Interval \* Ping NP Retry Count) + Ping NP Timeout**

- Use Witness HB Resource Settings

Use the same target host and service port as those of Witness HB which has already been configured.

- **Target Host**  
Sets the host address of the Web server to be connected.
- **Service Port**  
Sets the port number of the Web server to be connected.
- **Use SSL**  
Configures whether or not to use SSL for communicating the Web server. When the checkbox is selected, SSL is used, and when the checkbox is not selected, it is not used.

Use OpenSSL 1.0/1.1 for SSL. By default, the following libraries are used:

- libssl.so.10 (if you installed the rpm package of EXPRESSCLUSTER)
- libssl.so.1.0.0 (if you installed the deb package of EXPRESSCLUSTER)

To use other libraries, go to the **Encryption** tab and set **SSL Library** and **Crypto Library**.

- **Interval**  
Sets the interval for sending HTTP requests.
- **Timeout**  
Sets the timeout time from receiving an HTTP response to receiving the subsequent HTTP response.
- **HTTP timeout**  
Sets the timeout time from sending an HTTP request to receiving an HTTP response.
- **Initialize**  
Resets the settings of HTTP NP Properties to default values.

### Type

Set the type of network partition resolution I/F. **Ping** or **HTTP** is selectable.

### Target

Enter the information depending on the type you chose.

- **Ping**  
Enter the IP address of the device where you send a ping.
- **HTTP**  
Enter the DNS name or IP address of the Web server where you send an HTTP request.

### Server name

Select either **Use** or **Do Not Use**.

### Tuning

**Network Partition Resolution Tuning Properties** window is displayed.

### Network Partition Resolution Tuning Properties

**Network Partition Resolution Tuning Properties**

**Action at NP Occurrence**

Stop the cluster service and shutdown OS ▼

Initialize

OK Cancel Apply

- Action at NP Occurrence
  - Stop the cluster service  
Stop the cluster service of the server in network partition.
  - Stop the cluster service and shutdown OS  
Stops the cluster service of the server in network partition, and then shuts down the OS.
  - Stop the cluster service and reboot OS  
Stops the cluster service of the server in network partition, and then reboots the OS.
  - Sysrq Panic  
Performs a sysrq panic on the server in network partition.
  - Keepalive Reset  
Use this on the server in network partition to perform an OS reset by using the clpkhb and clpka drivers.
  - Keepalive Panic  
Use this on the server in network partition to perform an OS panic by using the clpkhb and clpka drivers.
  - BMC Reset  
Use this on the server in network partition to perform a hardware reset of the server by using the ipmi command.
  - BMC Power- Off  
Use this on the server in network partition to power off the server by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.
  - BMC Power Cycle  
Use this on the server in network partition to perform the Power Cycle (powering on/off) by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.
  - BMC NMI  
Use this on the server in network partition to generate NMI in the server by using the ipmi command. The behavior after the generation of NMI depends on the OS setting.
  - I/O Fencing(High-End Server Option)  
It can't be used.
- Initialize
  - Set the actions at NP occurrence to the default settings.

## 2.2.4 Timeout tab

Specify values such as time-out on this tab.

Cluster Properties | cluster

Info Interconnect NP Resolution **Timeout** Port No. Port No.(Mirror) Port No.(Log) Monitor Recovery  
Alert Service WebManager Alert Log Delay Warning Mirror Agent Mirror Driver JVM Monitor Extension

**Server Sync Wait Time\***  min

**Heartbeat**

**Interval\***  sec

**Timeout\***  sec

**Server Internal Timeout\***  sec

### Server Sync Wait Time (0 to 99)

For the time specified here, the server will wait at startup until other servers are started.

### Heartbeat

Heartbeat interval and heartbeat time-out.

- **Interval** (1 to 99)  
Interval of heartbeats
- **Timeout** (2 to 9999)

A failed server is determined if there is no response for the time specified here.

- This time-out should be longer than the interval.
- To perform the shutdown monitoring (see [Monitor tab](#)), this time-out should be longer than the time it takes to shut down applications and the operating system.
- When a hybrid disk resource is used, the time-out value must be longer than the value specified at the cluster partition I/O time-out in the **mirror agent** tab.

### Server Internal Timeout (1 to 9999)

The timeout to be used in the EXPRESSCLUSTER Server internal communications that are performed while an EXPRESSCLUSTER command is executed, or an operation is performed or a screen is displayed by Cluster WebUI.

### Initialize

Used for initializing the value to the default value. Click **Initialize** to initialize all the items to their default values.

## 2.2.5 Port No. tab

Specify TCP port numbers and UDP port numbers.

Cluster Properties | cluster

Info Interconnect NP Resolution Timeout **Port No.** Port No.(Mirror) Port No.(Log) Monitor Recovery  
Alert Service WebManager Alert Log Delay Warning Mirror Agent Mirror Driver JVM Monitor Extension

**TCP**

Server Internal Port Number\* 29001

Data Transfer Port Number\* 29002

WebManager HTTP Port Number\* 29003

**UDP**

Heartbeat Port Number\* 29002

Kernel Mode Heartbeat Port Number\* 29006

Alert Sync Port Number\* 29003

Initialize

OK Cancel Apply

### TCP

No TCP port numbers can be overlapped. When the Replicator is used, TCP port numbers on the **Port No.(Mirror)** tab and any mirror data port number of any mirror disk resources/hybrid disk resources cannot be overlapped.

- **Server Internal Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for internal communication.
- **Information Base Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for cluster information management.
- **Data Transfer Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for transactions such as applying and backing up the cluster configuration data, sending and receiving the license data and running commands.
- **WebManager HTTP Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for a browser to communicate with the EXPRESSCLUSTER Server.
- **API HTTP Port Number** (1 to 65535<sup>1</sup>)  
This port number is used when a Restful API client communicates with the EXPRESSCLUSTER Server.
- **API Server Internal Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for internal communication of Restful API.

### UDP

<sup>1</sup> It is strongly recommended not to use well-known ports, especially reserved ports from 1 to 1023.

No UDP port numbers can be overlapped. When the communication method for internal logs is UDP on the **Port No.(Log)** tab, UDP port numbers cannot be overlapped with the port numbers.

- **Heartbeat Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for heartbeat.
- **Kernel Mode Heartbeat Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for kernel mode heartbeat.
- **Alert Sync Port Number** (1 to 65535<sup>1</sup>)  
This port number is used for synchronizing alert messages among servers.

### Initialize

This is used for initializing the value to the default value. Click **Initialize** to initialize all items to their default values.

## 2.2.6 Port No. (Mirror) tab ~ For the Replicator/Replicator DR ~

Specify TCP port numbers.

The screenshot shows a window titled "Cluster Properties | cluster". It has several tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror) (selected), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, Alert Log, Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, and Extension. Under the "TCP" section, the "Mirror Agent Port Number\*" is set to "29004". There is an "Initialize" button and "OK", "Cancel", and "Apply" buttons at the bottom right.

### TCP

No TCP port numbers can be overlapped. TCP port numbers on the **Port No.** tab and any mirror data port number of any mirror disk resources/hybrid disk resources cannot be overlapped.

---

**Note:** Port numbers are not used when mirror disk resource/hybrid disk resource is not used.

---

- **Mirror Agent Port Number** (1 to 65535<sup>2</sup>)  
Mirror agent is a user mode module for controlling mirror disk resource/hybrid disk resource.  
The Mirror Agent uses this port number to communicate with servers.

### Initialize

Used for initializing the value to the default value. Click **Initialize** to initialize all the items to their default values.

---

<sup>2</sup> It is strongly recommended not to use well-known ports, especially reserved ports from 1 to 1023.

## 2.2.7 Port No. (Log) tab

Specify the communication method for internal logs.

The screenshot shows a window titled "Cluster Properties | cluster" with a close button (X) in the top right corner. Below the title bar is a tabbed interface with the following tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log) (selected), Monitor, Recovery, Alert Service, WebManager, Alert Log, Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, and Extension. The main content area is divided into two sections. The first section, "Communication Method for Internal Logs", contains three radio buttons: "UDP", "UNIX Domain" (which is selected), and "Message Queue". The second section, "Port Number", contains a text input field with the value "0". At the bottom left is an "Initialize" button, and at the bottom right are "OK", "Cancel", and "Apply" buttons.

### Communication Method for Internal Logs

- UDP  
Use UDP for the communication method for internal logs.
- UNIX Domain  
Use UNIX Domain for the communication method for internal logs.
- Message Queue  
Use Message Queue for the communication method for internal logs.

### Port No. (1 to 65535)

This is the port number used when UDP is selected for the communication method for internal logs.

### Initialize

Used for initializing the value to the default value. Click **Initialize** to initialize all the items to their default values.

## 2.2.8 Monitor tab

Configure the settings for monitoring. For details about the shutdown monitor and reboot limit, see "4. *Monitor resource details*" in this guide.

Cluster Properties | cluster

Info Interconnect NP Resolution Timeout Port No. Port No.(Mirror) Port No.(Log) **Monitor** Recovery  
Alert Service WebManager Alert Log Delay Warning Mirror Agent Mirror Driver JVM Monitor Extension

**Shutdown Monitor**

☐ Always execute  
☒ Execute when the group deactivation has been failed  
☐ Not execute

Method\*

Operation at Timeout Detection\*

Enable SIGTERM handler ☐

Timeout ☒ Use Heartbeat Timeout  
☐ Set Timeout  sec

**System Resource**

Collect the System Resource Information ☐

### Shutdown Monitor

Monitors whether or not the operating system is stalling when an EXPRESSCLUSTER command to shut down the cluster or servers is run.

The cluster service forcibly resets the operating system or performs a panic of the operating system if it determines the OS stall. Server panic can be set when the monitoring method is keepalive.

- **Always execute:**

If selected, the shutdown monitor is performed. For the heartbeat time-out, specify a longer time than the time required to shut down every application and the operating system (see "*Timeout tab*").

- **Execute when the group deactivation has been failed:**

The shutdown monitor is applied only when a group cannot be deactivated. For the heartbeat time-out, specify a longer time than the time required to shut down every application and the operating system (see "*Timeout tab*"). If you use shared disks or mirror disks, it is recommended to select **Execute when the group deactivation has been failed**.

- **Not execute:**

If selected, the shutdown monitor is not performed.

- **Method**

Select the shutdown monitor method from:

- \* softdog

- \* ipmi
- \* ipmi (High-End Server Option)
- \* keepalive

For details about the shutdown monitoring method, see "*Shutdown monitoring*" in "*Shutdown monitoring method*" in "*7. Information on other settings*" in this guide.

– **Operation at Timeout Detection**

Selects the operation performed when the operating system is determined to be stalled. This can be set only when the monitoring method is keepalive.

- \* RESET  
Resets the server.
- \* PANIC  
Performs a panic of the server.

– **Enable SIGTERM handler**

Select this to enable SIGTERM handler when performing the shutdown monitor.

For details about the SIGTERM settings, see "*Shutdown monitoring*" in "*Setting of SIGTERM*" in "*7. Information on other settings*" in this guide.

---

**Note:** If you select ipmi in **Method** and set **Enable SIGTERM handler** to **Off**, this may be reset even if the operating system is successfully shut down.

---

– **Use Heartbeat Timeout**

Select this for heartbeat time-out to work in conjunction with shutdown monitoring time-out.

– **Timeout (2 to 9999)**

Specify a time-out when the heartbeat time-out value is not used as shutdown monitoring time-out.

A value equal to or smaller than the heartbeat timeout value must be specified to prevent both systems from activating when a failover occurs upon detection of a server down.

## System Resource

Select whether to collect system resource information.

System resource information is collected regularly so as to improve system operability. System resource information is useful for investigating the operation status of EXPRESSCLUSTER, and makes it easy to determine the cause of a failure attributable to a shortage of system resources.

- When the check box is selected:  
System resource information related to the CPU, memory, processes, and others is collected regularly while the cluster is running.  
The collected system resource information are collected as a log by the clplogcc command or Cluster WebUI.

Specify type 1 to collect the log by the `clplogcc` command; specify Pattern 1 to collect the log by the Cluster WebUI. For details about log collection, see "[Collecting logs \(clplogcc command\)](#)" in "[8. EXPRESSCLUSTER command reference](#)" in this guide, and the online manual.

A disk area of 450 MB or more is required to store the resource information, depending on the system operating conditions such as the number of processes that are running.

To use this feature, a zip (unzip) package tool is required on each server.

- When the check box is cleared:  
No system resource information is collected.

## 2.2.9 Recovery tab

Configure the settings for cluster recovery.

The screenshot shows the 'Cluster Properties | cluster' dialog box with the 'Recovery' tab selected. The tabs include Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, API, Encryption, Alert Log, Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, Oracle Clusterware Linkage, Cloud, and Extension.

**Action When the Cluster Service Process Is Failure\***: Shut down the OS

**Recovery Action for HA Agents**

**Max Restart Count\***: 3 time

**Recovery Action over Max Restart Count\***: No operation

**Action at Group Resource Activation or Deactivation Stall\***: Stop the cluster service and shutdown OS

**Disable the Final Action when OS Stops Due to Failure Detection**: Detailed Settings

**Disable Shutdown When Multi-Failover-Service Detected**: Detailed Settings

**Initialize** button

**OK**, **Cancel**, **Apply** buttons

### Action When the Cluster Service Process Is Failure

Specify the action when a cluster service process error occurs.

- Shut down the OS  
Shut down the OS.
- Reboot the OS  
Reboot the OS.
- Sysrq Panic  
Performs a sysrq panic on the server in network partition..
- Keepalive Reset  
Use this on the server in network partition to perform an OS reset by using the `clpkhb` and `clpka` drivers.

- **Keepalive Panic**  
Use this on the server in network partition to perform an OS panic by using the clpkhb and clpka drivers.
- **BMC Reset**  
Use this on the server in network partition to perform a hardware reset of the server by using the ipmi command.
- **BMC Power Off**  
Use this on the server in network partition to power off the server by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.
- **BMC Power Cycle**  
Use this on the server in network partition to perform the Power Cycle (powering on/off) by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.
- **BMC NMI**  
Use this on the server in network partition to generate NMI in the server by using the ipmi command. The behavior after the generation of NMI depends on the OS setting.
- **I/O Fencing(High-End Server Option)**  
It can't be used.

#### **Recovery Action for HA Agents**

- **Max Restart Count (0 to 99)**  
Specify the max restart count when an HA Agent error has occurred.
- **Recovery Action over Max Restart Count**  
Specify the action when an HA Agent error has occurred.
  - No operation
  - Stop the cluster service  
Stops the cluster service of the server that detected an error.
  - Stop the cluster service and shutdown OS  
Stops the cluster service of the server that detected an error, and then shuts down the OS.
  - Stop the cluster service and reboot OS  
Stops the cluster service of the server that detected an error, and then reboots the OS.

---

**Note:** The HA process is used with the system monitor resources, process resource monitor resource, JVM monitor resources, and the system resource information collection function.

---

#### **Action at Group Resource Activation or Deactivation Stall**

Specify the action to apply in the event of an activation/deactivation stall of a group resource.

- **Stop cluster service and shutdown OS**  
Stops the cluster service of the server that stalled, and then shuts down the OS.
- **Stop cluster service and reboot OS**  
Stops the cluster service of the server that stalled, and then restarts the OS.
- **Sysrq Panic**  
Performs a sysrq panic on the server that stalled.
- **Keepalive Reset**

Use this on the server that stalled to perform an OS reset by using the clpkhb and clpka drivers.

- Keepalive Panic

Use this on the server that stalled to perform an OS panic by using the clpkhb and clpka drivers.

- BMC Reset

Use this on the server that stalled to perform a hardware reset of the server by using the ipmi command.

- BMC Power- Off

Use this on the server that stalled to power off the server by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.

- BMC Power Cycle

Use this on the server that stalled to perform the Power Cycle (powering on/off) by using the ipmi command. The OS may be shut down depending on how the ACPI of OS is configured.

- BMC NMI

Use this on the server that stalled to generate NMI in the server by using the ipmi command. The behavior after the generation of NMI depends on the OS setting.

- I/O Fencing(High-End Server Option)

It can't be used.

- No Operation (Operates as an activity or deactivity failure)

Use this to perform recovery upon the detection of an activation/deactivation failure of a group resource. For details on the recovery operation, see "[Recovery Operation tab](#)" in "[Resource Properties](#)" in "[3. Group resource details](#)" in this guide.

---

**Note:** If a stall occurs with "Nothing (handle a stall as an activation/deactivation failure)" specified, the effect on the group resources is undefined, so we do not recommend changing the setting to "Nothing (handle a stall as an activation/deactivation failure)".

If you do specify "Nothing (handle a stall as an activation/deactivation failure)", set the recovery operation upon the detection of an activation/deactivation failure of a group resource as described below.

Activation/Deactivation Retry Threshold: 0

Failover Threshold: 0

Final Action: Action that accompanies the OS stop

---

### Disable the Final Action when OS Stops Due to Failure Detection

Click **Detailed Settings** to set suppression of the final action which accompanies the OS stop caused by error detection.

**Detailed Settings**

Final Action When OS Stops Due to All Server Shutdown

**Group Resource When Activation Failure Detected** ☐

**Group Resource When Deactivation Failure Detected** ☐

**Monitor Resource When Failure Detected** ☐

- **Group Resource When Activation Failure Detected**

If the final action caused by an activation error detection in a group resource accompanies the OS stop, the final action is suppressed if all other servers are stopped.

- **Group Resource When Deactivation Failure Detected**

If the final action caused by a deactivation error detection in a group resource accompanies the OS stop, the final action is suppressed if all other servers are stopped.

- **Monitor Resource When Failure Detected**

If the final action caused by an error detection in a monitor resource accompanies the OS stop, the final action is suppressed if all other servers are stopped.

---

**Note:**

- If errors were detected on multiple servers almost at the same time, and the final action was taken for those servers, the final action which accompanies the OS stop may be taken for all the servers even if the final action caused by an error detection in a monitor resource is set to be suppressed.
  - The message receive monitor resource does not become the target for which the final action caused by error detection is suppressed.
  - The following situations lead to an OS stop during the final action when an activation/deactivation error is detected in a group resource and during the final action when a monitor resource error is detected.
    - Cluster service stop and OS shutdown
    - Cluster service stop and OS restart
    - sysrq panic
    - keepalive reset
    - keepalive panic
    - BMC reset
    - BMC power off
    - BMC power cycle
    - BMC NMI
-

### Disable Shutdown When Multi-Failover-Service Detected

Click **Detailed Settings** to suppress the shutdown of all servers upon detection of both-system activation.

### Server Group Survives When Multi-Failover-Service Detected

Select one server group. The shutdown of the server, which belongs to the server group selected when the both-system activation of the failover group was detected, is suppressed. When the both-system activation is detected among servers in the selected server group, both of the servers will be shut down. If you want to suppress the shutdown in this case, make the settings to disable shutdown when the following double activation is detected.

### Server Survives When Multi-Failover-Service Detected

Select one server. The shutdown of the server, selected when the both-system activation of the failover group was detected, is suppressed.

If a server group to which shutdown is not executed when Multi-Failover is detected is set, it is possible to select only a server belonging to the set server group. If no server group is set, all the servers can be selected.

---

**Note:** When the both-system activation is detected, the group statuses will be inconsistent among the servers, and failover and failback operations will be able to fail.

If a group status mismatch occurs, the following alert log is output:

Type: Warning

Module name: rc

Event ID: 503

Message: A mismatch in the group %1 status occurs between the servers. A mismatch in the group %1 status occurs between the servers.

---

## 2.2.10 Alert Service tab

Configure the settings for the mail report function, the network warning light, alert report destination, and SNMP trap transmission.

To use the mail report function, register the Alert Service license.

To use the network warning light, register the Alert Service license.

**Note:** To use the mail report function and the network warning light, purchase the EXPRESSCLUSTER X Alert Service 4.3 for Linux.

The screenshot shows the 'Cluster Properties' dialog box with the 'Alert Service' tab selected. The dialog has a dark header bar with the title 'Cluster Properties | cluster' and a close button. Below the header is a tabbed interface with the following tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service (selected), WebManager, API, Encryption, Alert Log, Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, Cloud, and Extension. The 'Alert Service' tab contains several sections: 'Enable Alert Setting' with a checkbox and an 'Edit' button; 'Mail Report' with fields for 'E-mail Address', 'Subject' (containing 'EXPRESSCLUSTER'), 'Mail Method' (a dropdown menu showing 'MAIL'), and an 'SMTP Settings' button; 'SNMP Trap' with a 'Destination Settings' button; 'Output the log level to syslog' with a checked checkbox; 'Use Chassis Identify' with a checkbox, two radio buttons ('Execute Repeatedly' is selected), and an 'Interval' field set to '120' seconds; and 'Use Network Warning Light' with a checkbox. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

### Enable Alert Setting

Configure whether to modify the alert destination from the default value. To modify the alert report destination, click **Edit** to configure the address.

By canceling **Enable Alert Setting**, the modified destination turns to the default value temporarily.

For details about the default alert destination, see "*Messages reported by syslog, alert, mail, SNMP trap, and Message Topic*" in "10. Error messages" in this guide.

### E-mail Address (Within 255 bytes)

Enter the e-mail address to which the report is sent. If more than two e-mail addresses are set, delimit the address by semicolon.

**Subject (Within 127 bytes)**

Enter the subject title for the e-mail message.

**Mail Method**

Configure the methods to send mail.

- **MAIL**  
This method uses the mail command. Check that a mail is sent to the mail address by using the mail command in advance.
- **SMTP**  
This method allows for sending mail by directly communicating with the P server.

**Destination Settings**

Configure the SNMP trap transmission function. Click **Settings** to configure the SNMP trap transmission destination.

**Output Log Level to syslog**

Add Log Level to the syslog messages which EXPRESSCLUSTER put out while it is in operation.

**Use Chassis Identify**

Configure whether or not to enable **Use Chassis Identify**.

**Execute Repeatedly**

Repeat Chassis Identify Command.

- Interval (1 to 999)

Set the interval of Chassis Identify Command.

**Do not Excute Repeatedly**

Not repeat Chassis Identify Command.

**Use Network Warning Light**

Specify whether to use a network warning light (specified by NEC) controlled by network. Enter an IP address in server properties.

**Change Alert Destination**

Click **Edit** to display the **Change Alert Destination** dialog box.

**Change Alert Destination**

EditAddRemove

Messages

Module	ID	Destination
No messages		

OKCancelApply

### Add

Click this to select the event ID and the module type for which you want to customize the report destinations. Click **Add** to open the **Enter the Message** dialog box.

**Enter the message**

CategoryCore Modules

Module Type\*apisv

Event ID\*1

Destination

☒ System Log☒ Alert Logs☐ Mail Report☐ SNMP Trap☐ Message Topic☐ Alert Extension

Command

EditAddRemove

No commands

OKCancel

### Category

Select a major category of the module type.

### Module Type (Within 31 bytes)

Select the name of module type that you want to change the destination address.

### Event ID

Enter the event type of the module type for which you want to change the destination address. For details about the event ID, see "*Messages reported by syslog, alert, mail, SNMP trap, and Message Topic*" in "10. *Error messages*" in this guide.

### Destination

Select the destination.

- System Log  
This sends message to syslog of the OS.
- Alert Logs  
This sends message to the alert log.
- Mail Report  
This sends message by using the mail report function.
- Message Topic  
This sends message to Amazon SNS.
- Alert Extension  
This sends message by the Alert Extension function. Modify the extension settings using **Add** and **Edit**.

### Add

Add a command of the alert extension function. Click **Add** to open the **Enter Command** dialog box. Up to 4 commands can be registered with one event ID.

### Command (Within 511 bytes)

Enter a command such as SNMP trap to execute reporting with the absolute path. The execution results of the specified command cannot be shown.

- Keyword  
If you specify `%%MSG%%`, the body message of the target event ID is inserted.  
You cannot specify multiple `%%MSG%%` for one command.  
Configure within 511 bytes including the description of `%%MSG%%`. Since blank characters can be included in `%%MSG%%`, if you specify this for an argument of commands, specify this as `"%%MSG%%"`.

#### Configuration example

```
/usr/local/bin/snmpttrap -v1 -c HOME 10.0.0.2 0 10.0.0.1 1 0 ' ' 1 s "%MSG  
↔ %"
```

### **Remove**

Click this to remove a command of alert extension function. Select the command and then click **Remove**.

### **Edit**

Click this to modify a command of alert extension function. Select the command and then click **Edit**.

## **SMTP Settings**

Click **SMTP Settings** to display the **SMTP Settings** dialog box.

The **SMTP Settings** dialog box contains the following elements:

- Mail Charset\***: A dropdown menu.
- Send Mail Timeout\***: A text input field containing "30" and a unit label "sec".
- Subject Encode**: A checkbox.
- Buttons**: "Edit", "Add", and "Remove" buttons.
- SMTP Server List**: A table with two columns: **Priority** and **SMTP Server**. The table is currently empty, showing "No SMTP Server".
- Navigation**: Up and down arrow buttons, and an "Initialize" button.
- Footer**: "OK", "Cancel", and "Apply" buttons.

### **Mail Charset (Within 127 bytes)**

Configure the character set of the e-mails sent for mail report.

### **Send Mail Timeout (1 to 999)**

Configure the timeout value for communicating with the SMTP server.

### **Subject Encode**

Select whether or not to encode the subject of e-mails.

### **SMTP Server List**

Use this button to display a SMTP server that is configured. Four SMTP servers can be configured in this version.

### **Add**

Use this button to add a SMTP server. Click **Add** to display the **Enter the SMTP Server** dialog box.

### **Remove**

Use **Remove** to remove the SMTP server settings.

### **Edit**

Use **Edit** to modify the SMTP server settings.

Enter the SMTP Server

SMTP Server*	<input type="text"/>
SMTP Port*	<input type="text" value="25"/>
Sender Address	<input type="text"/>
Enable SMTP Authentication	<input type="checkbox"/>
Authentication Method	<input type="text" value="LOGIN"/> <input type="button" value="v"/>
User Name	<input type="text"/>
Password	<input type="text"/> <input type="button" value="Change"/>

**SMTP Server (Within 255 bytes)**

Configure the IP address or host name of the SMTP server.

**SMTP Port (1 to 65535)**

Configure the port number of the SMTP server.

**Sender Address (Within 255 bytes)**

Configure the address from which an e-mail of mail report is sent.

**Enable SMTP Authentication**

Configure whether or not to enable SMTP authentication.

**Method**

Select a method of SMTP authentication.

**User Name (Within 255 bytes)**

Configure the user name used for SMTP authentication.

**Password (Within 255 bytes)**

Configure the password used for SMTP authentication.

The **Destination Settings** dialog box features a dark header with the title. Below the header, there are three buttons: **Edit**, **Add**, and **Remove**. A section labeled **Destination** contains a table with the following headers: **Destination Server**, **SNMP Port**, **SNMP Version**, and **SNMP Community Name**. The table currently shows a single entry: **No Destination**. At the bottom right of the dialog are three buttons: **OK**, **Cancel**, and **Apply**.

### Destination

Displays the set SNMP trap transmission destinations. With this version, up to 32 SNMP trap transmission destinations can be set.

### Add

Adds an SNMP trap transmission destination. Click **Add** to display the Change SNMP Destination dialog box.

### Remove

Use **Remove** to remove the SNMP trap transmission destination settings.

### Edit

Use **Edit** to modify the SNMP trap transmission destination settings.

The **Enter Destination** dialog box has a dark header with the title. It contains four labeled input fields: **Destination Server\*** (text box), **SNMP Port\*** (text box with value 162), **SNMP Version** (dropdown menu with value v2c), and **SNMP Community Name\*** (text box with value public and a dropdown arrow). At the bottom right are **OK** and **Cancel** buttons.

### Destination Server (Within 255 bytes)

Configure the name of the SNMP trap transmission destination server.

### SNMP Port No. (1 to 65535)

Configure the port number of the SNMP trap transmission destination.

### SNMP Version

Configure the SNMP version of the SNMP trap transmission destination.

**SNMP Community Name (Within 255 bytes)**

Configure the SNMP community name of the SNMP trap transmission destination.

**2.2.11 WebManager tab**

Use this tab to configure the settings for the WebManager Server.

**File Size**  MB

**Integrated WebManager**

**Connection IP address**

ⓘ If OS Authentication Method is configured, it is recommended to configure HTTPS for Communication Method.

**Enable WebManager Service**

Enables the WebManager Service.

- When the check box is selected:  
The WebManager service is enabled.
- When the check box is not selected:  
The WebManager service is disabled.

**Communication Method**

- HTTP

No encryption is used for communicating with a client.

- HTTPS

Encryption is used for communicating with a client.

#### Accessible number of clients (1 to 999)

Limits the number of concurrent requests from clients. If the concurrent requests exceed the limit, the overflowed requests are discarded.

#### Control connection by using password

Click **Settings** to show the **Password** dialog box.

**Password Settings**

**i** If OS Authentication Method is configured, it is recommended to configure HTTPS for Communication Method.

OK

Cancel

Apply

#### Cluster Password Method / OS Authentication Method

Choose a login method for Cluster WebUI from below.

- **Cluster Password Method**  
Performs authentication with an operation/reference password you set.
- **OS Authentication Method**  
Performs authentication with user and password of OS .

#### Cluster Password Method

- **Password for Operation**  
Set a password that must be entered to enable connection to the Cluster WebUI in operation mode, config mode, or simulate mode.  
Click **Change** to display the **Enter Password** dialog box.
- **Password for Reference**  
Set a password that must be entered to enable connection to the Cluster WebUI in reference mode.  
Click **Change** to display the **Enter Password** dialog box.

The image shows a dialog box titled "Enter password". It contains three input fields: "Old Password", "Password", and "Password Confirmation". At the bottom right, there are two buttons: "OK" and "Cancel".

- **Old Password: (Within 255 bytes)**  
Enter the current password. If the password is not set, leave it blank.
- **New Password: (Within 255 bytes)**  
Enter a new password. When deleting the old password, leave it blank.
- **Password Confirmation: (Within 255 bytes)**  
Enter the password again which you entered in **New Password**.  
Passwords can consist of one-byte upper- and lower-case letters, digits, symbols, and spaces (0x20 to 0x7E in ASCII code).

#### OS Authentication Method

Users must be registered to the server in advance to login to Cluster WebUI. More specifically, a group must be registered to the server and the users must belong to it as the control permission of a cluster is assigned per group,

#### Add

Used to add a group to **Authorized Group List**. The **Group Name** dialog box appears when **Add** is clicked. To add a group, the **Operation** checkbox must be selected.

A dialog box titled "Group Name" with a dark header bar. Below the header, the text "Group Name\*" is displayed in red. To the right of the text is a rectangular input field. At the bottom right of the dialog box are two buttons: "OK" and "Cancel".

- Group name (Within 255 bytes)  
Enter a group name to which you want to give permission. The permission will be applied to the users belong to the group you entered. Groups must be registered to a server in advance.

#### Remove

Used to delete a group from **Authorized Group List**. Select a group you want to delete from **Authorized Group List**, and click **Remove**.

#### Edit

Used to edit a group. Select a group you want to edit from **Authorized Group List**, and click **Edit**. The **Group Name** dialog box with the selected group entered appears. The control permission does not change in this procedure.

#### Operation

Set control permission to a group registered in **Authorized Group List**.

- When the checkbox is selected:  
Users belong to the group can control the cluster and view the status.
- When the checkbox is not selected:  
Users belongs to the group can view the status only.

#### Login Session Lifetime Period (0 to 52560)

Time frame of login session. If this value is set to zero (0), the period becomes limitless.

#### Automatic Logout Time Period (0 to 99999)

Sets wait time for automatic logout if there is no communication between Cluster WebUI and the Web-Manager server. If this value is set to zero (0), no automatic logout occurs.

#### Lockout Threshold (0 to 999)

Locks out a client IP address which fails to login continuously. The client cannot login until **Lockout Time** passes once a client is locked out. If this value is set to zero (0), no client IP address is not be locked out.

#### Lockout Time (1 to 99999)

Sets lockout time for a client IP address. Once the time passes, the lockout is automatically released.

#### Initialize

Restores the default value. If **Initialize** is clicked, the values of **Login Session Lifetime Period**, **Automatic Logout Time Period**, **Lockout Threshold** and **Lockout Time** are restored to the default values.

#### Control connection by using client IP address

If selected, accesses are controlled by client IP addresses.

- When the check box is selected:

**Add**, **Remove** and **Edit** are displayed.

- When the check box is not selected:  
**Add**, **Remove** and **Edit** are not displayed.

### Add

Use **Add** to add an IP address in **Connection Permit Client IP Address List**. Click **Add** to display the **IP Address** dialog box. Newly added IP addresses have the rights for the operation.

The image shows a dialog box titled "IP Address" with a dark header bar. Below the header, there is a label "IP Address\*" followed by a text input field. At the bottom right of the dialog, there are two buttons: "OK" and "Cancel".

- **IP Address (Within 80 bytes)**

Specify a client IP address that can be connected.

- IP address: 10.0.0.21
- Network address: 10.0.1.0/24

### Remove

Use **Remove** to remove an IP address from **Connection Permit Client IP Address List**. Select the IP address to be removed from **Connection Permit Client IP Address List** and then click **Remove**.

### Edit

Use **Edit** to edit an IP address. Select the IP address you want to edit from **Connection Permit Client IP Address List** and then click **Edit**. A dialog box where the specified IP address is preset is displayed. The rights for operating the edited IP addresses remain the same.

---

**Note:** The Connection Permit Client IP Address List specified here are also used to restrict connections for external operations using clprexec.

---

### Operation

Sets the operation rights for IP addresses that are registered in **Connection Permit Client IP Address List**.

- When the check box is selected:  
A client can operate a cluster and display its status.
- When the check box is not selected:  
A client can only view the status of a cluster.

### Output Cluster WebUI Operation Log

Allows you to output the operation log of Cluster WebUI.

For details, see "Maintenance Guide" - "The system maintenance information" - "Function for outputting the operation log of Cluster WebUI".

- If the check box is checked:

The operation log of Cluster WebUI is outputted.

- If the check box is not checked:  
The operation log of Cluster WebUI is not outputted.

#### Log output path (Within 255 bytes)

Specify the output destination directory of the Cluster WebUI operation log with an absolute path consisting of ASCII characters.

#### File Size (1 to 10)

Specify the size of Cluster WebUI operation log.

When the log data reaches the specified size, a rotation occurs. Up to five generations of the data are saved.

#### IP address for Integrated WebManager

Click **Settings** to open the IP address dialog box for the Integrated WebManager.

The dialog box titled "IP address for Integrated WebManager" contains the following elements:

- Buttons: "Add" and "Remove" at the top left.
- Section: "IP Address List" with a table below it.
- Table: A table with columns "Priority", "server1", and "server2". The "Priority" column is highlighted in blue. Below the table, it says "No IP addresses".
- Buttons: Up and down arrows below the table.
- Buttons: "OK", "Cancel", and "Apply" at the bottom right.

- **Add**

Add IP addresses for the Integrated WebManager. Click the column cell of each server and select or enter IP address for the IP address of each server. For the communication path not connected to some server, set blank to the server cell of which the server is not connected.

- **Remove**

Remove the communication path. Select the communication path to be removed and click **Remove**, then the selected path is removed.

- **Priority**

When multiple IP addresses for Integrated WebManager are configured, the communication path with the smallest number in the **Priority** column is used preferentially for the internal communication among cluster servers. When changing the priority, click the arrows to change the order of the selected row.

#### Tuning

Use **Tuning** to tune the WebManager Server. Clicking **Tuning** displays the **WebManager Tuning Properties** dialog box.

**WebManager Tuning Properties**

Behavior

<b>Client Session Timeout*</b>	30	sec
<b>Screen Data Refresh Interval*</b>	90	sec
<b>Mirror Agent Timeout*</b>	120	sec
<b>Time Limit For Keeping Log Files*</b>	600	sec
<b>Use Time Information Display Function</b>	<input checked="" type="checkbox"/>	

Initialize

OK

Cancel

Apply

- **Client Session Timeout** (1 to 999)  
Specify the client session time-out. A time-out is determined if the time specified here elapses after the last communication between the WebManager Server and the Cluster WebUI.
- **Reload Interval** (0 to 999)  
Specify the screen data update interval. At this time interval, the Cluster WebUI screen is refreshed.
- **Mirror Agent Timeout** (1 to 999)  
Set the data waiting time output from the mirror agent.
- **Time Limit For Keeping Log Files** (60 to 43200)  
Specify the expiration period for deleting log collection information that is temporarily stored on a server. Log information on a server will be deleted if the expiration period is exceeded after the dialog box prompting saving log collection information is displayed.
- **Use Time Info Display Function**  
Specify whether the time information display function is enabled or disabled.
  - When the check box is selected:  
The time information display function is enabled.
  - When the check box is not selected:  
The time information display function is disabled.
- **Initialize**  
Click **Initialize** to reset all settings on this dialog to default. Click **Initialize** to set all the items to their default values.

## 2.2.12 API tab

This tab allows you to set API services.

Cluster Properties | cluster

Info Interconnect NP Resolution Timeout Port No. Monitor Recovery Alert Service WebManager **API** Encryption Alert Log Delay Warning Disk Mirror Disk Account RIP(Legacy) Migration Cloud Extension

**Enable API Service** ☐

**Communication Method**

☐ HTTP

☒ HTTPS

Set a privilege per group ☐

Control connection by using client IP address ☐

Tuning

*! If enable API service, it is recommended to configure HTTPS for Communication Method.*

OK Cancel Apply

### Enable API Service

Enables API services.

- When the checkbox is selected:  
API services are enabled.
- When the checkbox is not selected:  
API services are disabled.

### Communication Method

- HTTP:  
Does not use encryption for client communication.
- HTTPS:  
Use encryption for client communication.

### Control a privilege of operating clusters per group

Allows you to set and control a privilege of operating clusters per group.

- If the check box is checked:  
**Add**, **Remove**, and **Edit** are displayed.
- If the check box is not checked:  
**Add**, **Remove**, or **Edit** is not displayed.

Login users must be registered beforehand in the server which issues the request. More specifically, a group must be registered to the server and the users must belong to it as the control permission of a cluster is assigned per group.

- If the server belongs to a work group:  
Register the same user name and group name in each of the servers which issues the request.

- If the server belongs to a domain:  
Register users and groups in the domain.

### Add

Allows you to add a group to **Authorized Group List**. Clicking **Add** displays the **Group Name** dialog box. Any group added here has the **Operation** box checked.

The image shows a dialog box titled "Group Name". It has a dark header bar with the title in white. Below the header, there is a text input field with the placeholder text "Group Name\*" in a light gray font. To the right of the input field are two buttons: "OK" and "Cancel".

- Group name (up to 255 bytes)  
Enter the name of a group. Users belonging to the group are to be given the permission.  
The group must be registered to a server in advance.

### Remove

Use this option to delete a group from **Authorized Group List**.

From **Authorized Group List**, select a group to be deleted. Then, click **Remove**.

### Edit

Use this option to edit a group. From **Authorized Group List**, select a group to be edited. Then click **Edit**. The **Group Name** dialog box appears with the selected group entered. Editing the group here does not change its operation right.

### Operation

Set operation rights for any of the groups registered in **Authorized Group List**.

- If the check box is checked:  
The users of the group can operate the cluster and obtain its status.
- If the check box is not checked:  
The users of the group can only obtain the status of the cluster.

### Control connection by using client IP address

Controls connections using client IP addresses.

- When the checkbox is selected:  
**Add**, **Remove** and **Edit** are displayed.
- When the checkbox is not selected:  
**Add**, **Remove** and **Edit** are not displayed.

### Add

Use **Add** to add an IP address in **Connection Permit Client IP Address List**. Click **Add** to display the **IP Address** dialog box. Newly added IP addresses have the rights for the operation.

The dialog box has a dark header bar with the text "IP Address". Below the header, the label "IP Address\*" is followed by a text input field. At the bottom right, there are two buttons: "OK" and "Cancel".

- **IP Address (Within 80 bytes)**

Specify a client IP address allowed for the connection.

- IP address: 10.0.0.21
- Network address: 10.0.1.0/24

### Remove

Use **Remove** to remove an IP address from **Connection Permit Client IP Address List**. Select the IP address to be removed from **Connection Permit Client IP Address List** and then click **Remove**.

### Edit

Use **Edit** to edit an IP address. Select the IP address you want to edit from **Connection Permit Client IP Address List** and then click **Edit**. A dialog box where the specified IP address is preset is displayed.

### Operation

Set operation rights for any of the IP addresses registered in **Connection Permit Client IP Address List**.

- When the check box is selected:  
A client can operate a cluster and display its status.
- When the check box is not selected:  
A client can only view the status of a cluster.

### Tuning.

Adjusts API services. Click **Tuning** to display **API Tuning Properties** dialog box.

The dialog box has a dark header bar with the text "API Tuning Properties". Below the header, there are three rows of settings:

Authentication Lockout Threshold*	3	time
HTTP Server Start Retry Count*	3	time
HTTP Server Start Interval*	5	sec

Below these settings is an "Initialize" button. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

- Authentication Lockout Threshold

Specify the number that counts continuous HTTP server authentication failures. If the counts reach this threshold, lockout is performed.

- HTTP Server Start Retry Count

Specify the retry number that counts API services failed to start a HTTP server.

- HTTP Server Start Interval

Specify the period of time between the time HTTP server start failure occurs and the time retry starts.

- Initialize

Use **Initialize** to restore the default value. All the items restore the default values when **Initialize** is clicked.

## 2.2.13 Encryption tab

Sets files and libraries used for encryption of the cluster elated services.

### Certificate File

Sets server certificate files used for connecting to a client. Server certificate files must be prepared at user side.

### Private Key File

Sets private key files used for connecting to a client. Private key files must be prepared at user side.

### SSL Library

Sets SSL library files used for encryption and selects SSL library files included in OpenSSL. Some settings such as installation locations need to be changed depending on the environment.

### Crypto Library

Sets Crypto library files used for encryption and selects Crypto library files included in OpenSSL. Some settings such as installation locations need to be changed depending on the environment.

## 2.2.14 Alert Log tab

Configure the settings for the alert log.

The screenshot shows the 'Cluster Properties' dialog box with the 'Alert Log' tab selected. The dialog has a title bar 'Cluster Properties | cluster' and a close button. Below the title bar is a tabbed interface with the following tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, Alert Log (selected), Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, and Extension. The 'Alert Log' tab contains the following settings:

- Enable Alert Service:** A checkbox that is checked.
- Max. Number to Save Alert Records\*:** A text input field containing the value '10000'.
- Alert Sync:** A section header.
- Method:** A dropdown menu showing 'unicast'.
- Communication Timeout\*:** A text input field containing the value '30', followed by the unit 'sec'.
- Initialize:** A button.
- OK, Cancel, Apply:** Buttons at the bottom right.

### Enable Alert Service

Select this to start alert service for the server.

- When the check box is selected:  
Alert service is enabled.
- When the check box is not selected:  
Alert service is disabled.

### Max. Number to Save Alert Records (1 to 99999)

Specify the maximum number of alert records that can be retained. Alert service for server can retain alert messages up to this number.

### Alert Sync: Method

This communication mode is used for Alert Log synchronization. Only unicast is available in **Method** list box for this version.

### Alert Sync: Communication Timeout (1 to 300)

Specify a communication time-out. A communication time-out is determined if the time specified here elapses after the last communication between Alert service and servers.

### Initialize

Click **Initialize** to reset all settings on this tab to default. Click **Initialize** to set all the items to their default values.

### 2.2.15 Delay Warning tab

Configure the settings for Delay Warning on this tab. For details, see "*Delay warning of monitor resources*" in "*Monitor resource*" in "4. *Monitor resource details*" in this guide.

The screenshot shows a window titled "Cluster Properties | cluster" with a close button (X) in the top right corner. Below the title bar is a tabbed interface with the following tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, Alert Log, Delay Warning (selected), Mirror Agent, Mirror Driver, JVM Monitor, and Extension. The "Delay Warning" tab is active, displaying two sliders. The first slider is labeled "Heartbeat Delay Warning" and has a blue arrow pointing to the 80% mark on a scale from 0 to 100. To the right of the slider is a text box containing "80" followed by a "%" symbol. The second slider is labeled "Monitor Delay Warning" and also has a blue arrow pointing to the 80% mark. To its right is another text box containing "80" followed by a "%" symbol. At the bottom left of the tab is an "Initialize" button. At the bottom right are three buttons: "OK", "Cancel", and "Apply".

#### Heartbeat Delay Warning (0 to 100)

Set a percentage of heartbeat time-out at which the heartbeat delay warning is issued. If the time for the percentage passes without any heartbeat response, the warning will be produced in an alert log. If you set 100, the warning will not be issued.

#### Monitor Delay Warning (0 to 100)

Set a percentage of monitor time-out at which the monitor delay warning is issued. If the time for the percentage passes without any monitor response, the warning will be produced in an alert log. If you set 100, the warning will not be issued.

---

**Note:** If you specify 0% for the delay warning, an alert log is shown in every heartbeat interval and monitor interval. Setting 0% allows you to see the time spent for monitoring. This will be helpful particularly in a test operation. Make sure not to set low values such as 0% in the production environment.

---

## 2.2.16 Mirror Agent tab ~ For the Replicator/Replicator DR~

Configure the settings for the Mirror Agent on this tab.

The screenshot shows the 'Cluster Properties' dialog box with the 'Mirror Agent' tab selected. The dialog has a title bar 'Cluster Properties | cluster' and a close button. Below the title bar is a tabbed interface with the following tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, Alert Log, Delay Warning, Mirror Agent (selected), Mirror Driver, JVM Monitor, and Extension. The 'Mirror Agent' tab contains the following settings:

- Auto Mirror Recovery**: ☒
- Collect Mirror Statistics**: ☒
- Receive Timeout\***:  sec
- Send Timeout\***:  sec
- Recovery Data Size\***:  KB
- Start Wait Time\***:  sec
- Cluster Partition I/O Timeout\***:  sec
- Recovery Limitation**:
  - ☐ On
  - ☒ Off
- Recovery Limitation Value**:  time

At the bottom left is an 'Initialize' button. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

### Auto Mirror Recovery

When the check box is selected, the mirror recovery is automatically performed if there is any difference between mirror disks on both servers. In some cases, you cannot perform the auto-mirror recovery even if this is selected. For details, see "*Automatically recovering from mirroring*" in "9. Troubleshooting" in this guide.

- When the check box is selected:  
The mirror recovery is automatically performed.
- When the check box is not selected:  
The mirror recovery is not automatically performed.

### Collect Mirror Statistics

This function can be used to collect and reference information about the mirroring performance. For details, see "Mirror statistics information collection function" in "The system maintenance information" in the "Maintenance Guide".

- When the check box is selected  
Mirror Statistics Collection is performed.
- When the check box is not selected  
Mirror Statistics Collection is not performed.

### Receive Timeout (1 to 600)

Set the time-out for the Mirror Agent waiting to receive data after establishing the connection.

**Send Timeout (1 to 600)**

Set the time-out for the Mirror Agent to send data to the Mirror Agent of the other server and wait it to be processed.

**Recovery Data Size (64 to 32768)**

**Specify the recovery data size.**

**Start wait time (10 to 600)**

For using a hybrid disk resource in a shared disk, set the waiting time to synchronize the starts of the servers connected to the shared disk. If another server does not start within the time configured here, the current right is obtained temporarily.

**Cluster partition I/O timeout (5 to 300)**

For using hybrid disk resource, set the timeout value for accessing the cluster partition.

- The time-out value must be smaller than the heartbeat time-out specified at the **Timeout** tab.

**Recovery Limitation**

Specify the retry count to perform mirror recovery again if the data has been updated during a mirror recovery.

- On (1 to 100)  
The mirror recovery retry is performed the times specified on the box.
- Off  
When there is update data, mirror recovery is performed until there is no difference.

**Initialize**

This is used to reset the values to the default value. Clicking **Initialize** sets all the items to their default values.

## 2.2.17 Mirror driver tab ~ For Replicator/Replicator DR ~

Configure the settings for the mirror driver on this tab.

Cluster Properties | cluster

Info Interconnect NP Resolution Timeout Port No. Port No.(Mirror) Port No.(Log) Monitor Recovery  
Alert Service WebManager Alert Log Delay Warning Mirror Agent Mirror Driver JVM Monitor Extension

Max. Number of Request Queues\* 2048

Difference Bitmap Size\* 1 MB

Difference Bitmap Refresh Interval\* 100 sec

Mirror Recovery I/O Size\* 4 KB

History Recording Area Size in Asynchronous Mode\* 100 MB

Operation at I/O Error Detection

Cluster Partition\* RESET

Data Partition\* RESET

Initialize

OK Cancel Apply

#### Max. Number of Request Queues (2048 to 65535)

Set the number of queues for mirror disk driver for queuing I/O requests from the upper system.

#### Difference Bitmap Size (1 to 5)

Users can specify the length of Record Area of the Difference Bitmap. Only when the mirror disk resource and/or hybrid disk resource do not exist in the cluster, the setting can be changed.

#### Difference Bitmap Refresh Interval (1 to 600)

Set the interval to check if the standby system writes the difference bitmap.

#### Mirror Recovery I/O size (4, 64)

Specify the size per I/O in the copy process of mirror recovery.

#### History Recording Area Size in Asynchronous Mode (1 to 200)

Specify the capacity of the mirror disk driver that, according to I/O requests from the upper system, stores data about unsent requests. Only when the mirror disk resource and/or hybrid disk resource do not exist in the cluster, the setting can be changed.

#### Operation at I/O Error Detection

- Cluster Partition  
Set an operation when an I/O error occurs in a cluster partition.
- Data Partition  
Set an operation when an I/O error occurs in a data partition.

#### Initialize

Use **Initialize** to reset the values to the default value. Click **Initialize** to set all the items to their default values.

## 2.2.18 JVM monitor tab

Configure detailed parameters for the JVM monitor.

**Note:** To display the **JVM monitor** tab on the the config mode of Cluster WebUI, you need to execute **Update Server Info** after the license for Java Resource Agent is registered.

Action Timeout\* 60 sec

### Java Installation Path (Within 255 bytes)

Set the Java VM install path used by the JVM monitor. Specify an absolute path using ASCII characters. Do not add "/" to the end of the path. This setting becomes common for all servers in the cluster. Specification example: /usr/java/jdk-9

### Maximum Java Heap Size (7 to 4096)

Set, in megabytes, the maximum Java VM heap size used by the JVM monitor (equivalent to -Xmx of the Java VM startup option). This setting becomes common for all servers in the cluster.

### Java VM Additional Option (Within 1024 bytes)

Set the Java VM startup option used by the JVM monitor. However, specify -Xmx in the [Maximum Java Heap Size]. This setting becomes common for all servers in the cluster. Specification example: -XX:+UseSerialGC

### Log Output Setting

Click the **Settings** button to open the Log Output Setting dialog box.

### Resource Measurement Setting

Click the **Settings** button to open the Resource Measurement Setting dialog box.

### Connection Setting

Click the **Settings** button to open the **Connection Setting** dialog box.

### Load Balancer Linkage Settings

Select the load balancer type and then click the **Settings** button. The **Load Balancer Linkage Settings** dialog box appears.

Select the load balancer type from the list. To perform load balancer linkage, select the load balancer you are using. To cancel the load balancer linkage, select **No linkage**.

### Action Timeout (30 to 300)

Set the timeout value of [Command] specified in each window of the JVM monitor. This setting becomes common for all the [Command] items.

### Log Output Setting

Clicking **Settings** displays the **Log Output Setting** dialog box.

Log Output Setting

Log Level\* INFO

Generation\* 10

Rotation Type

☒ File size

Max Size\* 3072 KB

☐ Time

Start Time 00:00

Interval 24 hours

Initialize

OK Cancel Apply

### Log Level

Select the log level of the log output by the JVM monitor.

### Generation (2 to 100)

Set the number of generations to be retained for log output by the JVM monitor. When **Period** is selected for **Rotation Type**, the rotation count is reset when cluster is suspended. Therefore, note that log files under the <EXPRESSCLUSTER\_install\_path>log\ha\jra increase per cluster suspend.

### Rotation Type

Select a rotation type for the log output by the JVM monitor. If you select **File Capacity** as the rotation type, set the maximum size (200 to 2097151), in kilobytes, for each log file such as the JVM operation log. If you select **Period** as the rotation type, set the log rotation start time in "hh:mm" format (hh: 0 to 23, mm: 0 to 59) and the rotation interval (1 to 8784) in hours.

### Initialize

Clicking **Initialize** returns the log level, generation, and rotation type items to their default values.

### Resource Measurement Setting [Common]

Clicking **Settings** displays the **Resource Measurement Setting** dialog box. For details about the scheme for error judgment by the JVM monitor, see "[Monitor resource details](#)".

The dialog box is titled "Resource Measurement Setting" and has two tabs: "Common" and "WebLogic". The "WebLogic" tab is selected. It contains several settings:

Setting	Value	Unit
Retry Count*	10	time
Failure Threshold*	5	time
<b>Interval</b>		
Memory Usage,Active Threads*	60	sec
The time and count in Full GC*	120	sec

At the bottom left is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

**Retry Count** (1 to 1440)

Set a resource measurement retry count to be applied if the JVM monitor fails in resource measurement.

**Error Threshold** (1 to 10)

Set the number of times abnormal judgment is performed when the usage of the Java VM or the application server resources collected by the JVM monitor via resource measurement continuously exceed the customer-defined threshold.

**Memory Usage, Active Threads** (15 to 600)

Set the interval at which the JVM monitor measures the memory usage and active thread count.

**The time and count in Full GC** (15 to 600)

Set the **interval** at which the JVM monitor measures the time and count in Full GC execution.

**Initialize**

Clicking **Initialize** returns the retry count, error threshold, and interval items to their default values.

**Resource Measurement Setting [WebLogic]**

Clicking **Settings** displays the **Resource Measurement Setting** dialog box. For details about the scheme for error judgment by the JVM monitor, see "Monitor resource details".

The image shows a 'Resource Measurement Setting' dialog box. It has two tabs: 'Common' and 'WebLogic', with 'WebLogic' currently selected. The dialog contains several input fields and buttons. The 'Retry Count\*' field has a value of 3 and is followed by the unit 'time'. The 'Failure Threshold\*' field has a value of 5 and is followed by the unit 'time'. There is a section header 'Interval' below these. Under 'Interval', there are two fields: 'The number of request\*' with a value of 60 and unit 'sec', and 'The average number of the request\*' with a value of 300 and unit 'sec'. At the bottom left is an 'Initialize' button. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

Field	Value	Unit
Retry Count*	3	time
Failure Threshold*	5	time
<b>Interval</b>		
The number of request*	60	sec
The average number of the request*	300	sec

**Retry Count** (1 to 5)

Set the resource measurement retry count to be applied if the JVM monitor fails in resource measurement.

**Error Threshold** (1 to 10)

Set the number of times abnormal judgment is to be performed when the usage of the Java VM or the application server resources collected by the JVM monitor via resource measurement continuously exceed the customer-defined threshold.

**The number of request** (15 to 600)

Set the interval at which the JVM monitor measures the number of work manager or thread pool requests during WebLogic monitor.

**The average number of the request** (15 to 600)

Set the interval at which the JVM monitor measures the average number of work manager or thread pool requests during WebLogic monitor. Set a value that is an integer multiple of the value set in **The number of request**.

**Initialize**

Clicking **Initialize** returns the retry count, error threshold, and interval items to their default values.

**Connection Setting**

Clicking **Settings** displays the Connection Settings dialog box.

The **Connection Setting** dialog box contains three input fields: **Management Port\*** with the value 25500, **Retry Count\*** with the value 3 and the unit 'time', and **Waiting time for reconnection\*** with the value 60 and the unit 'sec'. There is an **Initialize** button on the left and **OK**, **Cancel**, and **Apply** buttons on the right.

**Management Port** (1 to 65535)

Sets the port number internally used by the JVM monitor resource. Make sure not to set the port number that has been used by other functions or programs. This setting becomes common for all the servers in the cluster. Do not set 32768 to 61000.

**Retry Count** (1 to 5)

Set the retry count to be applied if connection to the monitor target Java VM fails.

**Waiting time for reconnection** (15 to 60)

Set the interval at which the JVM monitor retries connection if it fails in Java VM connection.

**Initialize**

Clicking **Initialize** sets the management port, retry count, and wait time for reconnection items to their default values.

**Load Balancer Linkage Settings**

If you select other than BIG-IP LTM as the load balancer type and then click the **Settings** button, the **Load Balancer Linkage Settings** dialog box appears.

The **Load Balancer Linkage Settings** dialog box contains the following fields: **Management Port for Load Balancer Linkage\*** (25550), **Health Check** section with **Health Check Linkage Function** (unchecked checkbox), **Directory containing HTML files**, **HTML File Name**, **HTML Renamed File Name**, **Retry Count for renaming** (3, time), and **Wait time for retry** (3, sec). There is an **Initialize** button on the left and **OK**, **Cancel**, and **Apply** buttons on the right.

**Management Port for Load Balancer Linkage** (1 to 65535)

Set the port number used by the load balancer linkage function. This setting becomes common to all the servers in the cluster. Do not set 32768 to 61000.

**Health Check Linkage Function**

Set whether to use the load balancer health check function if the monitor target Java VM detects a failure.

**Directory containing HTML files (Within 255 bytes)**

Set the directory in which the HTML file used by the load balancer health check function is stored. Specify an absolute path using ASCII characters. Do not add "/" to the end of the path.

**HTML File Name (Within 255 bytes)**

Set the HTML file name used by the load balancer health check function. Specify this filename using ASCII characters.

**HTML Renamed File Name (Within 255 bytes)**

Set the HTML renamed file name used by the load balancer health check function. Specify this file name using ASCII characters. Specify an HTML renamed file name that is different from the HTML file name.

**Retry count for renaming (0 to 5)**

Set the number of times HTML file renaming is retried if it fails.

**Wait time for retry (1 to 60)**

Set the interval at which HTML file renaming is retried if it fails.

**Initialize**

Clicking **Initialize** returns the management port for load balancer linkage, health check linkage function, directory containing HTML files, HTML file name, HTML renamed file name, retry count for renaming and wait time for retry items to their default values.

**Load Balancer Linkage Settings**

Select BIG-IP LTM as the load balancer type and then click the **Settings** button. The **Load Balancer Linkage Settings** dialog box appears.

**Load Balancer Linkage Settings**

**Management Port for Load Balancer Linkage\***

---

**Connect Info**

mgmt IP address\*

User Name\*

Password\*

Communications Port\*

**List of address of distributed nodes**

Server	IP Address
<input style="width: 95%;" type="text"/>	<input style="width: 95%;" type="text"/>

#### Management Port for Load Balancer Linkage (1 to 65535)

Set the port number used by the load balancer linkage function. This setting becomes common to all the servers in the cluster. Do not set 42424 to 61000.

#### mgmt IP address

Set the BIG-IP LTM IP address.

#### Management User Name (Within 255 bytes)

Set the BIG-IP LTM management user name.

#### Password (Within 255 bytes)

Set the BIG-IP LTM management user password.

#### Communications Port (1 to 65535)

Set the communication port number for BIG-IP LTM.

#### Add

Add the server name and IP address for the distributed node. For the server name, specify the EXPRESSCLUSTER server name. For the IP address, specify the value set to **Members** in **LocalTraffic - Pools:PoolList - Relevant pool - Members** of BIG-IP Configuration Utility. To change the value, select the line and directly edit the description.

## Remove

Remove the server name and IP address for the distributed node. Select the line to be removed and then click **Remove**. The selected server is removed.

## Initialize

Clicking **Initialize** returns the management port for load balancer linkage, management user name, and communication port number to the default settings.

## 2.2.19 Cloud tab

Configure functions for cloud environments.

The screenshot shows the 'Cluster Properties' dialog box with the 'Cloud' tab selected. The dialog has a title bar 'Cluster Properties | cluster' and a close button. Below the title bar is a tabbed interface with tabs: Info, Interconnect, NP Resolution, Timeout, Port No., Port No.(Mirror), Port No.(Log), Monitor, Recovery, Alert Service, WebManager, API, Encryption, Alert Log, Delay Warning, Mirror Agent, Mirror Driver, JVM Monitor, Cloud (selected), and Extension. The 'Cloud' tab contains two sections: 'Amazon SNS' and 'Amazon CloudWatch'. The 'Amazon SNS' section has a checkbox 'Enable Amazon SNS Linkage Function' (unchecked) and a text field 'TopicArn'. The 'Amazon CloudWatch' section has a checkbox 'Enable Amazon CloudWatch Linkage Function' (unchecked), a text field 'Namespace', and a numeric field 'Interval for Sending Metrics' set to '60' with a unit 'sec'. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

### Enable Amazon SNS linkage function

Enable or disable the Amazon SNS linkage function.

- If the check box is checked:  
The Amazon SNS linkage function is enabled.  
Amazon SNS is used as a destination of EXPRESSCLUSTER messages.  
By default, the messages are sent as shown in "10. *Error messages*": the "o"-marked lines of the [5] column in the table of "10.2. *Messages reported by syslog, alert, mail, SNMP trap, and Message Topic*".  
To send other messages:  
Go to **Cluster Properties** -> the **Alert Service** tab -> **Change Alert Destination** -> **Destination**, and then select **Message Topic**.
- If the check box is not checked:  
The Amazon SNS linkage function is disabled.

### TopicArn

Set TopicArn for the Amazon SNS linkage function.

### Enable Amazon CloudWatch linkage function

Enable or disable the Amazon CloudWatch linkage function.

- If the check box is checked:  
The Amazon CloudWatch linkage function is enabled.  
Amazon CloudWatch is informed of the monitoring process time taken by the monitor resource.
- If the check box is not checked:  
The Amazon CloudWatch linkage function is disabled.

---

**Note:** Using the Amazon CloudWatch linkage function requires turning on **Enable Amazon CloudWatch linkage function**, and enabling **Send polling time metrics** of the **Monitor (common)** tab for the target monitor resource.

---

### Namespace

Set Namespace for the Amazon CloudWatch linkage function.

### Interval for Sending Metrics

Set the frequency of informing Amazon CloudWatch of the monitoring process time taken by the monitor resource.

## 2.2.20 Extension tab

Other cluster functions are set.

## Reboot Limitation

If the final action at abnormality detection for group resources and monitor resources is specified with the setting accompanied by OS reboot, reboot may be repeated infinitely. By setting the reboot limit, you can prevent repeated reboots.

- **Max Reboot Count** (0 to 99)

Specify how many times the operating system can reboot. The number specified here is separately counted for group resource and monitor resource.

- **Max Reboot Count Reset Time** (0 to 999)

When the max reboot count is specified, if the operation from the cluster startup keeps running normally for the time specified here, the reboot count is reset. The time specified here is separately counted for group resource and monitor resource.

---

**Note:** If **Max Reboot Count Reset Time** is set to 0, the reboot count is not reset. If you want to reset the reboot count, use `clpregctrl` command.

---

## Use Forced Stop

Use this to select whether or not to enable the forced stop.

- On

If selected, the forced stop function is enabled.

For a physical machine, configure the settings on the **BMC** tab of the server properties. For a virtual machine (guest OS), configure the **Virtual Machine** setting on the **Info** tab of the server properties.

- Off

If selected, the forced stop function is disabled.

## Forced Stop Action

Specify an action of the forced stop.

- BMC Reset

Use this to perform a hardware reset of the server by using the `ipmitool` command.

- BMC Power Off

Use this to power off the server by using the `ipmitool` command. The OS may be shut down depending on how the ACPI of OS is configured.

- BMC Power Cycle

Use this to perform the Power Cycle (powering on/off) by using the `ipmitool` command. The OS may be shut down depending on how the ACPI of OS is configured.

- BMC NMI

Use this to generate NMI by using the `ipmitool` command. The performance after the generation of NMI depends on the OS setting.

## Forced Stop Timeout (0 to 99)

Configure the timeout value when performing Forced Stop. After the above commands are executed, activating failover groups starts when the time specified elapses

## Virtual Machine Forced Stop Setting

Configure forced stop for the virtual machine (guest OS). Click **Settings** to display the **Virtual Machine Forced Stop Setting** dialog box.

**Virtual Machine Forced Stop Setting**

**Virtual Machine Management Tool** vCenter

**Forced Stop**

Action Power Off

Timeout\* 30 sec

Command\* /usr/lib/vmware-vcli/apps/

**vCenter/SCVMM**

Host Name

User Name

Password Change

OK Cancel Apply

#### Virtual Machine Management Tool

- vCenter  
Select this when you want to use vCenter to control the virtual machine.

#### Forced Stop

- Action  
Specify the action performed upon a forced stop.
- poweroff  
Use this to power off the server by using the command specified in **Command**.
- Timeout (**0 to 99**)  
Set the timeout value to be used when performing a forced stop. After the above command is executed, the activation of failover groups starts when the time specified here elapses.
- Command (**Within 1023 bytes**)  
Specify the command for forced stop.

#### vCenter

- Host Name (**Within 255 bytes**)  
Specify the host name of the virtual machine management tool.
- User Name (**Within 255 bytes**)  
Specify the user name of the virtual machine management tool.
- Password  
Specify the password for the virtual machine management tool.

---

**Note:** Do not use a double quotation mark (") in the password.

---

### Execute Script for Forced Stop

Use this to select whether or not to execute a script for the forced stop.

- On  
If selected, the script is executed for the forced stop.
- Off  
If selected, the script is not executed.

### Script Settings

Make settings on the script for the forced stop. Click **Script Settings** play the **Edit Script** dialog box.  
The default script file names, **forcestop.sh**, are listed on **Scripts**.

### User Application

Use an executable file (executable shell script file or execution file) on the server as a script. For the file name, specify an absolute path or name of the executable file of the local disk on the server. If there is any blank in the absolute path or the file name, put them in double quotation marks (") as follows.

Example:

"/tmp/user application/script.sh"

Each executable file is not included in the cluster configuration information of the Cluster WebUI. They must be prepared on each server because they cannot be edited or uploaded by the Cluster WebUI.

### Path (Within 1023 bytes)

Specify a script to be executed (executable shell script file or execution file) when you select **User Application**.

### Script created with this product

Use a script file which is prepared by the Cluster WebUI as a script. You can edit the script file with the Cluster WebUI if you need. The script file is included in the cluster configuration information.

### Add

Use this button to add a script other than **forcestop.sh** script when you select **Script created with this product**.

---

**Note:**

Do not use 2-byte characters for the name of a script to be added.

Do not use "&( ampersand)" or "=" (equal sign)" for a script file name to be added.

---

**Remove**

Use this button to delete a script when you select **Script created with this product**. The **forcestop.sh** script cannot be deleted.

**View**

Click here to display the script file when you select **Script created with this product**.

**Edit**

Click here to edit the script file when you select **Script created with this product**. Click **Save** to apply the change. You cannot modify the name of the script file.

**Replace**

Click here to replace the contents of a script file with the contents of the script file which you selected in the **file selection** dialog box when you select **Script created with this product**. You cannot replace the script file if it is currently displayed or edited. Select a script file only. Do not select binary files (applications), and so on.

**Disable Group Failover When Execution Fails**

If a forced stop script fails, a failover is disabled. If the failover is controlled, no group starts at the failover destination. Check the failover source and if necessary, perform the group operation.

**Timeout (1 to 999)**

Specify the maximum time to wait for completion of script to be executed. The default value is set as 10.

**Use CPU Frequency Control**

Select the check box when you use CPU frequency control.

When CPU frequency control is used, the CPU frequency of the server where a failover group is activated is set to high, and that of the server where a failover group is stopped is set to low.

When CPU frequency control is performed by a command, the settings changed by the command are given higher priority regardless of whether the failover group is started or stopped. Note that the settings changed by the command or Cluster WebUI is discarded after the cluster is stopped/started or suspended/resumed, so that CPU frequency is controlled by the cluster.

- When the check box is selected  
CPU frequency control is performed.
- When the check box is cleared  
CPU frequency control is not performed.

---

**Note:** For using CPU frequency control, it is required that the frequency is changeable in BIOS settings and the CPU supports the frequency control by OS power management function and that kernel is supported.

---

**Start Automatically After System Down**

Set whether to prohibit automatic startup of the cluster service at the next OS startup when the server has been stopped by a means other than cluster shutdown or cluster stop, or when cluster shutdown or stop does not terminate normally.

For the conditions to prohibit automatic startup of the cluster service after system down, see "*Conditions for automatic startup prohibition*" in "7. *Information on other settings*".

### **Exclude Mount/Unmount Commands**

Specify the exclusion of mount and unmount of the file systems executed in disk resource, mirror disk resource, hybrid disk resource, NAS resource and VxVOL resource. If this option is selected, problems such as mount or unmount command failure can be avoided due to the /etc/mounttab lock. It may take time to activate and deactivate a resource if there are many resources because mount and unmount processes are executed in order.

- When the check box is selected:  
The exclusion is performed.
- When the check box is not selected:  
The exclusion is not performed.

### **Grace period of server group failover policy (0 to 99999)**

Specify the time by which a failover start is delayed when the automatic failover is performed between the server groups. After a server failure is detected and then the specified time elapses, the failover is performed.

If you specify 0, no delay occurs.

### **Disable cluster operation**

- Group Automatic Startup
  - When the checkbox is selected:  
The group does not start automatically.
  - When the checkbox is not selected:  
The group starts automatically.
- Recovery operation when a group resource activation error is detected
  - When the checkbox is selected:  
The recovery operation is disabled.
  - When the checkbox is not selected:  
The recovery operation is not disabled.
- Recovery operation when a group resource deactivation error is detected
  - When the checkbox is selected:  
The recovery operation is disabled.
  - When the checkbox is not selected:  
The recovery operation is not disabled.
- Recovery action when a monitor resource error is detected
  - When the checkbox is selected:  
The recovery action is disabled.
  - When the checkbox is not selected:  
The recovery action is not disabled.

---

**Note:** The **Recovery action when a monitor resource error is detected** feature does not support external monitor resources.

---

### **Cluster Statistics**

You can collect and see data on the cluster operation such as the required time of a group failover and that of resource activation.

For more information, see " Cluster statistics information collection function" in " The system maintenance information" in the " Maintenance Guide".

- When the check box is selected  
The cluster statistical information is collected.
  - **File Size** (1 to 99)  
Specify the size of the cluster statistical information file.  
When the collected information reaches the specified size, rotation occurs to save up to two generations of the data.
- When the check box is cleared  
The cluster statistical information is not collected.

### **Initialize**

Use **Initialize** to reset the values to the default value. Clicking **Initialize** sets all the items to their default values.

## 2.3 Server Common Properties

Configure setting information of all servers in Servers Properties.

### 2.3.1 Master server tab

Configure the priority order of the servers. All the registered servers are displayed. Master server is the server to keep the master of cluster configuration information. And also, it is the server of the highest priority order.

The screenshot shows a dialog box titled "Server Common Properties" with a close button (X) in the top right corner. Inside the dialog, there are two tabs: "Master server" (selected) and "Server group". Below the tabs, the text "Server Definitions" is displayed. A table with two columns, "Order" and "Name", is shown. The first row is labeled "Master server" and contains the value "server1". The second row is labeled "1" and contains the value "server2". Below the table, there are two buttons with up and down arrows. At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

Order	Name
Master server	server1
1	server2

#### Order

Used when changing the priority order of the servers. Select the server to be changed from the server definition list, and Click the arrows selected row moves.

## 2.3.2 Server group tab

Set server groups.

**Server Common Properties**

Master server | **Server group**

Properties | Rename | Add | Remove

Server Group Definitions

Name	Server
svg1	server1

OK Cancel Apply

### Add

Add server groups. The wizard windows for adding the server group is displayed. For the details, see "Creating the cluster configuration data" in "Installation and Configuration Guide".

### Remove

Then the selected server group is removed.

When the following conditions are matched, the server group cannot be removed.

Selected target	Conditions that the server group cannot be removed	Application method
Server group name	The server group is registered as the server group of the failover group.	Cluster stop Mirror agent stop Mirror agent start Cluster start

### Rename

The change server group name dialog box of the selected server group is displayed.

**Rename server group | svg1**

New name\*

OK Cancel

There are the following naming rules

Selected target	Naming rules	Application method
Server group name	<ul style="list-style-type: none"><li>• There are naming rules that are the same as the host name of TCP/IP that can be set by the OS.</li><li>• Up to 31 characters (31 bytes).</li><li>• Names cannot start or end with a hyphen (-) or a space.</li><li>• A name consisting of only numbers is not allowed.</li></ul>	Cluster stop Mirror agent stop Mirror agent start Cluster start

Names should be unique (case-insensitive) in the server group.

### Properties

Display the properties of the selected server group.

### Server Group Definition

Server Group Definition

Name\*

#### Name

Display the server group name.

#### Add

Add the selected server in **Available Servers** to **Servers that can run the Group**.

#### Remove

Remove the selected server in **Servers that can run the Group** from the list.

#### Order

Used when changing the priority order of the server. Select the server to be changed from **Servers that can run the Group** and click the arrows. The selected row moves.

#### Servers

Display the server names which belong to the server group.

## 2.4 Server properties

Configure individual settings on each server constructing the cluster in Server Properties.

### 2.4.1 Info tab

You can display the server name and make a change to a comment on this tab.

The screenshot shows a window titled "Server Properties | server1". It has five tabs: "Info", "Warning Light", "BMC", "Disk I/O Lockout", and "Proxy". The "Info" tab is selected. Inside the "Info" tab, there are several fields: "Name" with the value "server1", "Comment" with an empty text box, "Virtual machine" with an unchecked checkbox, "Type" with a dropdown menu showing a downward arrow, and "Forced Stop Setting" with a "Settings" button. At the bottom right of the window are three buttons: "OK", "Cancel", and "Apply".

#### Name

The selected server name is displayed. You cannot change the name here.

#### Comment (Within 127 bytes)

You can specify a comment for the server. Only alphanumeric characters are allowed.

#### Virtual Machine

Specify whether this server is a virtual machine (guest OS).

- On  
If selected, the server is a virtual machine (guest OS). You can configure this virtual machine.
- Off  
If selected, the server is a physical machine. You cannot configure a virtual machine.

#### Type

Specify the type of virtual infrastructure.

- vSphere  
Virtual infrastructure provided by VMware, Inc.
- KVM  
Linux kernel virtual infrastructure.
- XenServer  
Virtual infrastructure provided by Citrix Systems, Inc.
- Container  
Virtual infrastructure provided by Oracle Systems, Inc.
- Hyper-V

Virtual infrastructure provided by Microsoft Corporation.

- other  
Specify this option to use any other virtual infrastructure.

### Forced Stop Setting

Set the information about the virtual machine (guest OS). Click **Settings** to display the **Input for Virtual Machine name** dialog box.

A screenshot of a dialog box titled "Input for Virtual Machine Name" with a close button (X) in the top right corner. The dialog contains three input fields: "Virtual Machine Management Tool" (with a "Settings" button to its right), "Virtual Machine Name", and "Data Center". At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

### Virtual Machine Management Tool

Set the vCenter server that manages the virtual machine (guest OS). Click **Settings** to display the **Virtual Machine Forced Stop Setting** dialog box.

For more information on **Virtual Machine Forced Stop Setting**, refer to the description of the *"Extension tab"*.

### Virtual Machine name (Within 80 bytes)

Set the virtual machine (guest OS) name.

---

**Note:** Do not use a double quotation mark (") or percent sign (%) in the virtual machine name.

---

### Data Center (Within 80 bytes)

Set the name of the data center that manages the virtual machine (guest OS).

---

**Note:** Do not use a double quotation mark (") or percent sign (%) in the virtual machine name.

---

## 2.4.2 Warning Light tab

Set an IP address of warning light (specified by NEC) controlled by network.

Server Properties | server1

Info Warning Light BMC Disk I/O Lockout

## Add

Use **Add** to add an interface. Clicking **Add** displays the **Enter Alert Lamp** dialog box.

Enter Alert Lamp

Warning Light\* DN-1000S / DN-1000R / DN-1300GL

IP Address

Alert When Server Starts ☐

Voice File No.

Alert When Server Stops ☐

Voice File No.

OK Cancel

- **Warning Light**

Select the product number of the warning light you use. The products corresponding to each number are as follows.

Product Number	Product Name
DN-1000S/DN-1000R/DN-1300GL	DN-1000S/DN-1000R/DN-1300GL
DN-1500GL	DN-1500GL
NH-FB series/NH-FB1 series	NH-FB series/NH-FB1 series
NH-FV1 series	NH-FV1 series

- **IP Address (Within 80 bytes)**

Enter an IP address of the warning light.

**Note:** One warning light is required per one server. Do not set an IP address of the same warning light to multiple servers.

- **Playback of an audio file**

Playback of an audio file is enabled when DN1500GL or NH-FV1 series is selected as the warning light type.

If you change the warning light type to other than DN1500GL or NH-FV1 series after playback of an audio file was enabled, playback of an audio file will be disabled.

#### **Alert When Server Starts**

- When the check box is selected:  
Reproduces the audio file at server start. The audio file is reproduced only once.
- When the check box is not selected:  
Does not reproduce the audio file at server start.

#### **Voice File No. (DN1500GL:01 to 20, NH-FV1 series: 01 to 70)**

Set the number of the voice file to be played when the server starts

#### **Alert When Server Stops**

- When the check box is selected:  
Reproduces the audio file at server stop. The audio file is continuously reproduced until it is stopped manually.
- When the check box is not selected:  
Does not reproduce the audio file at server stop.

#### **Voice File No. (DN1500GL:01 to 20, NH-FV1 series: 01 to 70)**

Set the number of the voice file to be played when the server stops.

#### **Edit**

Use **Edit** to edit the warning light setting.

---

#### **Note:**

To play back the audio file, it must be registered in the network warning light.

For more information on audio file registration, refer to the instruction manual of the network warning light to be used.

Set the audio file number corresponding to the audio file that is registered for the network warning light.

---

### 2.4.3 BMC tab

Configure a LAN port for managing BMC when using the forced stop and the chassis identify.

Configure one for each server.

The screenshot shows the 'Server Properties | server1' dialog box with the 'BMC' tab selected. The dialog has tabs for 'Info', 'Warning Light', 'BMC', and 'Disk I/O Lockout'. Below the tabs, it says 'Register items you want to use'. Under the 'BMC' section, there are 'Edit', 'Add', and 'Remove' buttons. Below these is a table with columns 'No.', 'IP Address', and 'User Name'. The table is currently empty, showing 'No Bmcs'. At the bottom of the table are up and down arrow buttons. At the bottom right of the dialog are 'OK', 'Cancel', and 'Apply' buttons.

#### Add

Use this button to newly configure a server. Click **Add** to opens the **Enter BMC** dialog box.

The screenshot shows the 'Enter BMC' dialog box. It has fields for 'IP Address', 'User Name', 'Password', 'Forced Stop Action', 'Chassis Identify', 'Flash', and 'Turn off'. The 'Password' field is highlighted with a grey background and has a 'Change' button next to it. At the bottom right are 'OK' and 'Cancel' buttons.

- **IP Address (Within 80 bytes)**  
Enter the IP address set for the LAN port for managing BMC.
- **User Name (Within 255 bytes)**  
Enter the user name with administrator privilege from the user names configured in BMC.

If you do not enter anything, the argument of user name is not configured when the ipmitool command.  
The valid length of user name varies depending on the ipmitool command and the specification of BMC of the server.

- Password (**Within 255 bytes**)

Enter the password of the user configured above.

The valid length of password varies depending on the specifications of ipmitool command and the BMC of the server.

For more information on user name and password, refer to the manual of the server.

- Forced Stop Action (**Within 255 bytes**)

Enter a command of forced stop action.

For details, see "*Forced stop*" in "*7. Information on other settings*" in this guide.

- Flash (**Within 255 bytes**)

Enter a flashing command of chassis identify.

For details, see "*Chassis Identify*" in "*7. Information on other settings*" in this guide.

- Turn off (**Within 255 bytes**)

Enter a turn-off command of chassis identify.

For details, see "*Chassis Identify*" in "*7. Information on other settings*" in this guide.

## Remove

Use this button to remove the settings. Select the target setting, and then, click **Remove**.

## Edit

Use this button to modify the settings. Select the target setting, and then, click **Edit**. The **Enter BMC** dialog box is displayed.

When a cluster consists of the different types of servers and includes a server which does not have BMC function, do not configure the **BMC** tab for the server.

In such a configuration, if **Chassis Identify** and/or the forced stop function, the alert telling you "failed in the BMC action" is displayed.

## 2.4.4 Disk I/O Lockout tab

Configure the settings for disk I/O lockout devices.

Server Properties | server1

Info Warning Light BMC Disk I/O Lockout

Register items you want to use

Disk I/O Lockout List

Edit Add Remove

No.	Device
No Disk I/O Lockout	

↑ ↓

OK Cancel Apply

Add

Use **Add** to add lockout devices. Clicking **Add** displays the **Enter Disk I/O Lockout** dialog box.

A dialog box titled "Enter Disk I/O Lockout" with a close button (X) in the top right corner. It contains a text input field labeled "Device name" and two buttons at the bottom right: "OK" and "Cancel".

- Device Name (**Within 1023 bytes**)  
Enter a disk I/O lockout device.

Remove

Use **Remove** to remove lockout devices. Select the device to remove from the **Disk I/O Lockout List** device and then click **Remove**.

Edit

Use **Edit** to edit disk I/O lockout devices. Clicking **Edit** opens the **Enter Disk I/O Lockout** dialog box.

No.

Use the arrows to change the I/F number. Select the I/F you want to change from the I/F list and then click the arrows. The selected row moves up and down accordingly.

2.4.5 Proxy tab

Sets proxy information.

A screenshot of the "Server Properties | server1" window, specifically the "Proxy" tab. The window has a dark header bar with the title and a close button. Below the header, there are several tabs: "Info", "Warning Light", "BMC", "BMC(High-End Server Option)", and "Disk I/O Lockout". The "Proxy" tab is currently selected. Under the "Proxy" tab, there is a section for "Proxy Scheme\*" with a dropdown menu showing "None". Below this, there are two text input fields labeled "Proxy Server" and "Proxy Port". At the bottom right of the window, there are three buttons: "OK", "Cancel", and "Apply".

Proxy Scheme

Sets protocols you want to use.

- None: Proxy is used.
- HTTP: HTTP is used.

Proxy Server

Sets the DNS host name (or IP address) you want to connect.

### **Proxy Port**

Sets the port number you want to connect.

## 2.5 Group Properties

For more information, see "[3. Group resource details](#)" in this guide.

## 2.6 Group Resource Properties

For more information, see "[3. Group resource details](#)" in this guide.

## 2.7 Monitor Resource Properties

For more information, see "[4. Monitor resource details](#)" in this guide.

## 2.8 Parameters list

Parameters you can specify in the Cluster WebUI and their default values are listed below.

"How to change [1]-[11]" represents the way you apply changes of parameters on servers. Applicable method is marked with "✓."

Priority	How to apply
1	Uploading data and shutting down, restarting a cluster
2	Stopping a cluster, and stopping a mirror agent, and then uploading data
3	Uploading data after stopping a cluster
4	Uploading data after stopping a group
5	Uploading data after stopping a resource
6	Uploading data after suspending a cluster
7	Uploading data after suspending a monitor
8	Uploading data and restarting an Information Base service
9	Uploading data and restarting WebManager Server
10	Uploading data and restarting an API service
11	Uploading data only

When creating the cluster configuration data for the first time, see "Creating the Cluster configuration data" in the "Installation and Configuration Guide".

Final Action at Activation Failure	No operation (Do not activate the next resource.)						✓					
Execute Script before Final Action	Off											✓
Retry Count at Deactivation Failure	One time						✓					
Final Action at Deactivation Failure	Stop the cluster service and shut down the OS						✓					
Execute Script before Final Action	Off											✓
Details Tab												
Virtual Host Name	-					✓						
IP Address	-					✓						
DDNS Server	-					✓						
Port No.	53					✓						
Authentication Key Name	-					✓						
Authentication Key Value	-					✓						

## AWS Elastic IP resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
AWS elastic ip Resource Properties[15]												
Dependency Tab												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
Recovery Operation Tab												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Next resources are not activated.)						✓					
Execute Script before Final Action at Activation Failure	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster service and shut down OS.						✓					
Execute Script before Final Action at Deactivation Failure	Off											✓
Details Tab												
EIP ALLOCATION ID	-					✓						
ENI ID	-					✓						
AWS elastic ip Resource Tuning Properties												
Parameter Tab												
AWS CLI Timeout	100 seconds					✓						

[15] It does not apply to PPC64 and PPC64LE.

### AWS Virtual IP resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS virtual ip Resource Properties</b> [16]												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Next resources are not activated.)						✓					
Execute Script before Final Action at Activation Failure	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster service and shut down OS.						✓					
Execute Script before Final Action at Deactivation Failure	Off											✓
<b>Details Tab</b>												
IP Address	-					✓						
VPC ID	-					✓						
ENI ID	-					✓						
<b>AWS virtual ip Resource Tuning Properties</b>												
<b>Parameter Tab</b>												
AWS CLI Timeout	100 seconds					✓						

[16] It does not apply to PPC64 and PPC64LE.

### AWS DNS resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS DNS Resource Properties</b> [17]												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Next resources are not activated.)						✓					
Execute Script before Final Action at Activation Failure	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster service and shut down OS						✓					
Execute Script before Final Action at Deactivation Failure	Off											✓
<b>Details Tab</b>												
Hosted Zone ID	-					✓						
Resource Record Set Name	-					✓						
IP Address	-					✓						
TTL	300 seconds					✓						
Delete a resource record set at deactivation	Off											✓
<b>AWS DNS Resource Tuning Properties</b>												
<b>Parameter Tab</b>												
AWS CLI Timeout	100 seconds											✓

[17] It does not apply to PPC64 and PPC64LE.

### Azure probe port resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Azure probe port Resource Properties</b> [18]												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Not activate next resources)						✓					
Execute Script before Final Action	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster daemon and shut down OS.						✓					
Execute Script before Final Action	Off											✓
<b>Details Tab</b>												
Probeport	-					✓						
Azure probe port Resource Tuning Properties												
Parameter Tab												
Probe wait timeout	30 seconds					✓						

[18] It does not apply to PPC64 and PPC64LE.

### Azure DNS resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Azure DNS Resource Properties</b> [19]												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	1 time						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (not activate next resource)						✓					
Execute Script before Final Action at Activation Failure	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure Detection	Stop the cluster service and shut down OS.						✓					
Execute Script before Final Action at Deactivation Failure	Off											✓
<b>Details Tab</b>												
Record Set Name	-					✓						
Zone Name	-					✓						
IP Address	-					✓						
TTL	3600 seconds					✓						
Resource Group Name	-					✓						
User URI	-					✓						
Tenant ID	-					✓						
File Path of Service Principal	-					✓						
Thumbprint of Service Principal	-					✓						
Azure CLI File Path	-					✓						
Delete a record set at deactivation	On											✓
Azure DNS Resource Tuning Properties												
Parameter Tab												
Azure CLI Timeout	100 seconds											✓

[19] It does not apply to PPC64 and PPC64LE.

### Google Cloud Virtual IP resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Google Cloud Virtual IP Resource Properties</b> <sup>[20]</sup>												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Not activate next resources)						✓					
Execute Script before Final Action	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster daemon and shut down OS.						✓					
Execute Script before Final Action	Off											✓
<b>Details Tab</b>												
Port Number	-					✓						
Google Cloud Virtual IP Resource Tuning Properties												
Parameter Tab												
Health check timeout	30 seconds					✓						

[20] It does not apply to PPC64 and PPC64LE.

### Google Cloud DNS resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Google Cloud DNS Resource Properties</b> <sup>[61]</sup>												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	1 time						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (not activate next resource)						✓					
Execute Script before Final Action at Activation Failure	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure Detection	Stop the cluster service and shut down OS.						✓					
Execute Script before Final Action at Deactivation Failure	Off											✓
<b>Details Tab</b>												
Zone Name	-					✓						
DNS Name	-					✓						
IP Address	-					✓						
TTL	3600 seconds					✓						
Delete a record set at deactivation	On											✓

[61] It does not apply to PPC64 and PPC64LE.

## Oracle Cloud Virtual IP resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Oracle Cloud Virtual IP Resource Properties</b> <sup>[21]</sup>												
<b>Dependency Tab</b>												
Follow the default dependence	On (No default dependence)						✓					
Dependent Resources (Add, Remove)	-						✓					
<b>Recovery Operation Tab</b>												
Retry Count at Activation Failure	5 times						✓					
Maximum Failover Count	1 time						✓					
Final Action at Activation Failure	No Operation (Not activate next resources)						✓					
Execute Script before Final Action	Off											✓
Retry Count at Deactivation Failure	zero						✓					
Final Action at Deactivation Failure	Stop the cluster daemon and shut down OS.						✓					
Execute Script before Final Action	Off											✓
<b>Details Tab</b>												
Port Number	-					✓						
Oracle Cloud Virtual IP Resource Tuning Properties												
<b>Parameter Tab</b>												
Health check timeout	30 seconds					✓						

[21] It does not apply to PPC64 and PPC64LE.

## Monitor resource (common)

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
Add monitor resource	-						✓					
Remove Monitor Resource	-						✓					
<b>Monitor Resources Common Properties</b>												
<b>Info Tab</b>												
Name	-						✓					
Comment	-											✓
<b>Recovery Action Tab</b>												
Edit Script												
Select User Application	-											✓
Enter application path (Edit)												
Select Script created with this product	-											✓
Script content (Edit)												
Timeout	5 seconds											✓

## Disk monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Disk Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	One time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					
<b>Monitor(special) Tab</b>												
Method	READIO_DIRECT											✓
Monitor Target	-											✓
Monitor Target RAW Device Name	-											✓
I/O size	512 bytes											✓
Action When Diskfull is Detected	The recovery action enabled											✓

## IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
IP Monitor Resource Properties												
Monitor(common)Tab												
Interval	30 seconds						✓					
Timeout	30 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
Monitor(special) Tab												
IP Address(Add, Remove, Edit)	-											✓
Recovery Action Tab												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

## Virtual IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
Virtual IP Monitor Resource Properties [22]												
Monitor(common)												
Interval	3 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	Virtual IP resource name						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	.						✓					
Send polling time metrics	Off											✓
Recovery Action Tab												
Recovery Target	Virtual IP resource name						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[22] You can upload the data if a cluster is suspended. However, you need to stop and resume the cluster to apply the changed setting.

## PID monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Pid Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	5 seconds						✓					
Timeout	60 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	3 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

## User mode monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>User mode Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	3 seconds						✓					
Timeout	90 seconds						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Nice Value	-20						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Use heartbeat interval and timeout	On						✓					
Method	keepalive						✓					
Operation at Timeout Detection	RESET						✓					
Open/Close Temporary File	Off						✓					
Write	Off						✓					
Size	10000 bytes						✓					
Create Temporary Thread	Off						✓					

### NIC Link Up/Down monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>NIC Link Up/Down Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	10 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	3 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Recovery Target	-											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	zero						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

### Multi target monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Multi Target Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	30 seconds						✓					
Timeout	30 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Recovery Target	-											✓
<b>Multi Target Monitor Resource Tuning Properties</b>												
<b>Parameter Tab</b>												
Error Threshold	Same as Number of Members											✓
Specify Number	64											✓
Warning Threshold	Off											✓
Specify Number	-											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

**Mirror disk monitor resource**

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Mirror Disk Monitor Resource Properties [23]</b>												
<b>Monitor(common) Tab</b>												
Interval	10 seconds						✓					
Timeout	60 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Mirror Disk Resource	Mirror disk resource name											✓
<b>Recovery Action Tab</b>												
Execute Script before Final Action	Off											✓

[23] It does not apply to PPC64 and PPC64LE.

**Mirror disk connect monitor resource**

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Mirror Disk Connect Monitor Resource Properties [24]</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	zero						✓

Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Hybrid Disk Resource	Hybrid disk resource name											✓
<b>Recovery Action Tab</b>												
Execute Script before Final Action	Off											✓

[26] It does not apply to PPC64 and PPC64LE.

### ARP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
ARP Monitor Resource Properties												
<b>Monitor(common) Tab</b>												
Interval	30 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Target Resource	-						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

## Custom monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Custom Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Send polling time metrics	Off											✓
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
<b>Monitor(special) Tab</b>												
Monitor Script Path Type	Script created with this product						✓					
Monitor Script Type	Synchronous						✓					
Wait a period of time for Application/Script monitor to start	0											✓
Log Output Path	Blank (/dev/null)						✓					
Rotate Log	Off						✓					
Rotation Size	1000000						✓					
Normal Return Value of Monitor Script	0						✓					
Wait for activation monitoring to stop before stopping the cluster	Off											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop group						✓					

## Volume manager monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Volume Manager Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	1						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Volume Manager	LVM						✓					
Target Name	-											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is not a cluster)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	0 times (if the recovery target is not a cluster)						✓					
Execute Script before Final Action	On											✓
Final Action	No action is taken.						✓					

## VM monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>VM Monitor Resource Properties</b> [27]												
<b>Monitor(common) Tab</b>												
Interval	10 seconds						✓					
Timeout	30 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	.						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Wait Time When External Migration Occurs	15 seconds											
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time						✓					
Execute Script before Final Action	On											✓
Final Action	No action is taken.						✓					

[27] It does not apply to PPC64 and PPC64LE.

## Message receive monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Message Receive Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	10 seconds						✓					
Timeout	30 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	.						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Category	NIC						✓					
Keyword	-						✓					
Change the monitor status to abnormal as a result of a predictive failure detected by BMC	Off						✓					
Change the monitor status to abnormal as a result of a performance deterioration failure	Off						✓					
<b>Recovery Action Tab</b>												
Recovery Action	Run failover for recovery target						✓					
Recovery Target	-						✓					
Execute migration before Failover	Off						✓					
Execute Failover to outside the Server Group	Off						✓					
Execute Script before Recovery Action	Off											✓
Final Action	No Operation						✓					

### Dynamic DNS monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Dynamic DNS Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	Dynamic DNS resource name						✓					
Nice Value	0						✓					
<b>Failure Detection Server</b>												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Recovery Action Tab</b>												
Recovery Target	Dynamic DNS resource name						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Three times						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	One time (if the recovery target is not a cluster)						✓					
Execute Script before Final Action	Off											✓
Final Action	No action is taken.						✓					

### Process name monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Process Monitor Resource Properties</b>												
<b>Monitor(common) tab</b>												
Interval	5 seconds						✓					
Timeout	60 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	3 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice value	0						✓					
<b>Failure Detection Server</b>												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Process name	-						✓					
Minimum Monitored Process Count	1						✓					
<b>Recovery Action tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (When the recovery target is other than the cluster)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

## BMC monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>BMC Monitor Resource Properties</b> [28]												
<b>Monitor (common) Tab</b>												
Interval	5 seconds						✓					
Timeout	60 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Retry Count	zero						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Recovery Action Tab</b>												
Recovery Action	Final action only						✓					
Recovery Target	LocalServer						✓					
Recovery Script Execution Count	-						✓					
Execute Script before Reactivation	-											✓
Maximum Reactivation Count	-						✓					
Execute Script before Failover	-											✓
Execute migration before Failover	-						✓					
Maximum Failover Count	-						✓					
Execute Script before Final Action	Off											✓
Final Action	I/O fencing						✓					

[28] It does not apply to PPC64 and PPC64LE.

## DB2 monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>DB2 Monitor Resource Properties</b> [29]												
<b>Monitor (common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor (special) Tab</b>												
Monitor Level	Level 2 (monitoring by update/select)						✓					
Database Name	-						✓					
Instance	db2inst1						✓					
User Name	db2inst1						✓					
Password	-						✓					
Table	db2watch						✓					
Character Set	ja_JP.eucJP						✓					
Library Path	/opt/ibm/db2/V11.1/lib64/libdb2.so						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster daemon and shutdown OS						✓					

[29] It does not apply to PPC64LE.

## FTP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>FTP Monitor Resource Properties</b> <sup>[30]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	3 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
IP Address	127.0.0.1											✓
Port Number	21											✓
User Name	-											✓
Password	-											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[30] It does not apply to PPC64 and PPC64LE.

## HTTP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>HTTP Monitor Resource Properties</b> <sup>[31]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	10 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	3 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Connecting Destination	localhost											✓
Port	80											✓
Request URI	-											✓
Protocol	HTTP											✓
Request Type	HEAD											✓
User Name	-											✓
Password	-											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[31] It does not apply to PPC64 and PPC64LE.

IMAP4 monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
IMAP4 Monitor Resource Properties <sup>[32]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	3 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
IP Address	127.0.0.1											✓
Port Number	3306											✓
User Name	-											✓
Password	-											✓
Authentication Method	AUTHENTICATE LOGIN											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[32] It does not apply to PPC64 and PPC64LE.

## MySQL monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>MySQL Monitor Resource Properties</b> [33]												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Monitor Level	Level 2 (monitoring by update/select)						✓					
Database Name	-						✓					
IP Address	127.0.0.1						✓					
Port	3306						✓					
User Name	-						✓					
Password	-						✓					
Table	mysqlwatch						✓					
Storage Engine	InnoDB						✓					
Library Path	/usr/lib64/mysql/libmysqlclient.so.20						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[33] It does not apply to PPC64 and PPC64LE.

## NFS monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>NFS Monitor Resource Properties</b> [34]												
<b>Monitor(common) Tab</b>												
Interval	30 seconds						✓					
Timeout	60 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	5 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Share Directory	-											✓
NFS Server	127.0.0.1											✓
NFS Version	v4											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[34] It does not apply to PPC64 and PPC64LE.

ODBC monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
ODBC Monitor Resource												
<b>Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓

Port	25											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[41] It does not apply to PPC64 and PPC64LE.

## SQL Server monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>SQL Server Monitor Resource Properties</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Monitor Level	Level 2 (monitoring by update/select)						✓					
Database Name	-						✓					
Server Name	Localhost						✓					
User Name	SA						✓					
Password	-						✓					
Table	sqlwatch						✓					
ODBC Driver Name	ODBC Driver 13 for SQL Server						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

### Sybase monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Sybase Monitor Resource Properties</b> <sup>[42]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Monitor Level	Level 2 (monitoring by update/select)						✓					
Database Name	-						✓					
Database Server Name	-						✓					
User Name	sa						✓					
Password	-						✓					
Table	sybwatch						✓					
Library Path	/opt/sap/OCS-16_0/lib/libsybdb64.so						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[42] It does not apply to PPC64 and PPC64LE.

### Tuxedo monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Tuxedo Monitor Resource Properties</b> <sup>[43]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Application Server Name	BBL											✓
Config File	-											✓
Library Path	/home/Oracle/tuxedo/tuxedo12.1.3.0.0/lib/libtux.so											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[43] It does not apply to PPC64 and PPC64LE.

## WebLogic monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>WebLogic Monitor Resource Properties</b> <sup>[44]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server							✓					
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
IP Address	127.0.0.1											✓
Port	7002											✓
Monitor Method	RESTful API											✓
Protocol	HTTP											✓
User Name	weblogic											✓
Password	-											✓
Account Shadow	Off											✓
On Config File	-											✓
On Key File	-											✓
Off User Name	weblogic											✓
Off Password	weblogic											✓
Authority Method	DemoTrust											✓
Key Store File	-											✓
Domain Environment File	/home/Oracle/product/Oracle_Home/user_projects/domains/base_domain/bin/setDomainEnv.sh											✓
Additional Command Option	-Dwls.offline.log=disable -Duser.language=en_US											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[44] It does not apply to PPC64 and PPC64LE.

**WebSphere monitor resource**

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>WebSphere Monitor Resource Properties</b> <sup>[45]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	2 times						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server							✓					
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Application Server Name	server1											✓
Profile Name	default											✓
User Name	-											✓
Password	-											✓
Install Path	/opt/IBM/WebSphere/AppServer											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[45] It does not apply to PPC64 and PPC64LE.

**WebOTX monitor resource**

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Tuxedo Monitor Resource Properties</b> <sup>[46]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	120 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	Off						✓					
Do not Execute Recovery Action at Timeout Occurrence	Off						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server							✓					
Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)							✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Connecting Destination	localhost											✓
Port	6212											✓
User Name	-											✓
Password	-											✓
Install Path	/opt/WebOTX											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	Zero (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Stop cluster service and shutdown OS						✓					

[46] It does not apply to PPC64 and PPC64LE.

## JVM monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>JVM Monitor Resource Properties[47]</b>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump files of the monitor process at timeout occurrence	Off						✓

Failure Detection Server	All servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Monitor NIC Link Up/Down	Off											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	0 times						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (when the recovery target is other than the cluster)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (when the recovery target is other than the cluster)						✓					
Execute Script before Final Action	Off											✓
Final Action	No operation						✓					

## AWS Elastic IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS elastic IP Monitor Resource Properties</b> <sup>[50]</sup>												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	awseip						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can start (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Action when AWS CLI command failed to receive response	Disable recovery action(Do nothing)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Do Operation						✓					

[50] It does not apply to PPC64 and PPC64LE.

### AWS Virtual IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS virtual ip Monitor Resource Properties</b> [51]												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓

Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	awsvip						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can start (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Action when AWS CLI command failed to receive response	Disable recovery action(Do nothing)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	Do Operation						✓					

[51] It does not apply to PPC64 and PPC64LE.

### AWS AZ monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS AZ Monitor Resource Properties</b> [52]												
<b>Monitor(common)Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Availability Zone	-						✓					
Action when AWS CLI command failed to receive response	Disable recovery action(Do nothing)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	0 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[52] It does not apply to PPC64 and PPC64LE.

## AWS DNS monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>AWS DNS Monitor Resource Properties</b> <sup>[53]</sup>												
<b>Monitor (Common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	60 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	awsdns						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor (Special) Tab</b>												
Monitor Resource Record Set	On											✓
Action when AWS CLI command failed to receive response	Disable recovery action(Do nothing)											✓
Check Name Resolution	On											✓
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[53] It does not apply to PPC64 and PPC64LE.

## Azure probe port monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Azure probe port Monitor Resource Properties</b> <sup>[54]</sup>												
<b>Monitor (common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	azurepp						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Action when Probe port wait timeout	Disable recovery action(Display warning)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[54] It does not apply to PPC64 and PPC64LE.

### Azure load balance monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Azure load balance monitor resource Properties</b> [55]												
<b>Monitor (common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed))						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor (special) Tab</b>												
Target Resource	-						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-											
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[55] It does not apply to PPC64 and PPC64LE.

### Azure DNS monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Azure DNS Monitor Resource Properties</b> [56]												
<b>Monitor (Common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	60 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	azuredns						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor (Special) Tab</b>												
Check Name Resolution	On											✓
<b>Recovery Action Tab</b>												
Recovery Action	azuredns						✓					
Recovery Script Execution Count	0 time						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[56] It does not apply to PPC64 and PPC64LE.

## Google Cloud Virtual IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Google Cloud Virtual IP Monitor Resource Properties</b> [57]												
<b>Monitor (common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	gcvip						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Action when Health check wait timeout	Disable recovery action(Do nothing)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[57] It does not apply to PPC64 and PPC64LE.

## Google Cloud load balance monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Google Cloud load balance monitor resource Properties</b> [58]												
<b>Monitor(common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed))						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Target Resource	-						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[58] It does not apply to PPC64 and PPC64LE.

### Google Cloud DNS monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Google Cloud DNS Monitor Resource Properties</b> <sup>[62]</sup>												
<b>Monitor (Common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	60 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	gcdn						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Recovery Action Tab</b>												
Recovery Action	gcdn						✓					
Recovery Script Execution Count	0 time						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[62] It does not apply to PPC64 and PPC64LE.

### Oracle Cloud Virtual IP monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
<b>Oracle Cloud Virtual IP Monitor Resource Properties</b> <sup>[59]</sup>												
<b>Monitor (common) Tab</b>												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Active (fixed)						✓					
Target Resource	ocvip						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
<b>Monitor(special) Tab</b>												
Action when Health check wait timeout	Disable recovery action(Do nothing)						✓					
<b>Recovery Action Tab</b>												
Recovery Target	-						✓					
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[59] It does not apply to PPC64 and PPC64LE.

Oracle Cloud load balance monitor resource

Parameters	Default	How to change										
		1	2	3	4	5	6	7	8	9	10	11
Oracle Cloud load balance monitor resource Properties[60]												
Monitor(common) Tab												
Interval	60 seconds						✓					
Timeout	180 seconds						✓					
Collect the dump file of the monitor process at timeout occurrence	Off						✓					
Do Not Retry at Timeout Occurrence	On						✓					
Do not Execute Recovery Action at Timeout Occurrence	On						✓					
Retry Count	1 time						✓					
Wait Time to Start Monitoring	0 seconds						✓					
Monitor Timing	Always (fixed)						✓					
Target Resource	-						✓					
Nice Value	0						✓					
Failure Detection Server												
Failure Detection Server	All Servers						✓					
Servers that can run the Group (Add, Remove)	-						✓					
Send polling time metrics	Off											✓
Monitor(special) Tab												
Target Resource	-						✓					
Recovery Action Tab												
Recovery Target	-											
Recovery Script Execution Count	zero						✓					
Execute Script before Reactivation	Off											✓
Maximum Reactivation Count	3 times (if the recovery target is other than clusters)						✓					
Execute Script before Failover	Off											✓
Execute migration before Failover	Off						✓					
Maximum Failover Count	1 time (if the recovery target is other than clusters)						✓					
Execute Script before Final Action	Off											✓
Final Action	No Operation						✓					

[60] It does not apply to PPC64 and PPC64LE.

## 2.9 Upper limits of registration

	version	You can register up to
Cluster	4.0.0-1 or later	1
Server	4.0.0-1 or later	32
Server group	4.0.0-1 or later	9
Group	4.0.0-1 or later	128
Group resource (Per group)	4.0.0-1 or later	256
Monitor resource	4.0.0-1 or later	512
Heartbeat resource	4.0.0-1 or later	128
BMC Heartbeat resource	4.0.0-1 or later	1
Witness heartbeat resource	4.0.0-1 or later	1
Oracle Clusterware Synchronization Management monitor resource	4.0.0-1 or later	1
Network partition resolution resource	4.0.0-1 or later	64
Mirror disk resources and hybrid disk resources (Per cluster) in total	4.0.0-1 or later	32
Mirror disk connect	4.0.0-1 or later	16

## GROUP RESOURCE DETAILS

This chapter provides information on group resources that constitute a failover group.

For overview of group resources, see "Configuring a cluster system" in the "Installation and Configuration Guide".

*This chapter covers:*

- *3.1. Group resources and supported EXPRESSCLUSTER versions*
- *3.2. Attributes common to group resources*
- *3.3. Group common properties*
- *3.4. Group properties*
- *3.5. Resource Properties*
- *3.6. Understanding EXEC resources*
- *3.7. Understanding Disk resource*
- *3.8. Understanding Floating IP resource*
- *3.9. Understanding Virtual IP resources*
- *3.10. Understanding Mirror disk resources*
- *3.11. Understanding Hybrid disk resources*
- *3.12. Understanding NAS resource*
- *3.13. Understanding Volume manager resources*
- *3.14. Understanding VM resources*
- *3.15. Understanding Dynamic DNS resources*
- *3.16. Understanding AWS Elastic IP resources*
- *3.17. Understanding AWS Virtual IP resources*
- *3.18. Understanding AWS DNS resources*
- *3.19. Understanding Azure probe port resources*
- *3.20. Understanding Azure DNS resources*
- *3.21. Understanding Google Cloud Virtual IP resources*
- *3.22. Understanding Google Cloud DNS resources*
- *3.23. Understanding Oracle Cloud Virtual IP resources*

## 3.1 Group resources and supported EXPRESSCLUSTER versions

The following is the number of group resources that can be registered with a group:

Version	Number of group resources(per group)
4.0.0-1 or later	256

Currently supported group resources are:

Group resource name	Abbreviation	Functional overview	Supported version
Exec resource	exec	See " <a href="#">Understanding EXEC resources</a> "	4.0.0-1 or later
Disk resource	disk	See " <a href="#">Understanding Disk resource</a> "	4.0.0-1 or later
Floating IP resource	fip	See " <a href="#">Understanding Floating IP resource</a> "	4.0.0-1 or later
Virtual IP resource	vip	See " <a href="#">Understanding Virtual IP resources</a> "	4.0.0-1 or later
Mirror disk resource	md	See " <a href="#">Understanding Mirror disk resources</a> "	4.0.0-1 or later
Hybrid disk resource	hd	See " <a href="#">Understanding Hybrid disk resources</a> "	4.0.0-1 or later
NAS resource	nas	See " <a href="#">Understanding NAS resource</a> "	4.0.0-1 or later
Volume manager resource	volmgr	See " <a href="#">Understanding Volume manager resources</a> "	4.0.0-1 or later
VM resource	vm	See " <a href="#">Understanding VM resources</a> "	4.0.0-1 or later
Dynamic DNS resource	ddns	See " <a href="#">Understanding Dynamic DNS resources</a> "	4.0.0-1 or later
AWS Elastic IP resource	awseip	See " <a href="#">Understanding AWS Elastic IP resources</a> "	4.0.0-1 or later
AWS Virtual IP resource	awsvip	See " <a href="#">Understanding AWS Virtual IP resources</a> "	4.0.0-1 or later
AWS DNS resource	awsdns	See " <a href="#">Understanding AWS DNS resources</a> "	4.0.0-1 or later
Azure probe port resource	azurepp	See " <a href="#">Understanding Azure probe port resources</a> "	4.0.0-1 or later
Azure DNS resource	azuredns	See " <a href="#">Understanding Azure DNS resources</a> "	4.0.0-1 or later
Google Cloud Virtual IP resource	gcvip	See " <a href="#">Understanding Google Cloud Virtual IP resources</a> "	4.2.0-1 or later
Google Cloud DNS resource	gcdns	See " <a href="#">Understanding Google Cloud DNS resources</a> "	4.3.0-1 or later
Oracle Cloud Virtual IP resource	ocvip	See " <a href="#">Understanding Oracle Cloud Virtual IP resources</a> "	4.2.0-1 or later

The group resources that currently support dynamic resource addition are as follows:

Group resource name	Abbreviation	Functional overview	Supported version
Exec resource	exec	See " <a href="#">Understanding EXEC resources</a> "	4.0.0-1 or later
Disk resource	disk	See " <a href="#">Understanding Disk resource</a> "	4.0.0-1 or later
Floating IP resource	fip	See " <a href="#">Understanding Floating IP resource</a> "	4.0.0-1 or later
Virtual IP resource	vip	See " <a href="#">Understanding Virtual IP resources</a> "	4.0.0-1 or later
Volume manager resource	volmgr	See " <a href="#">Understanding Volume manager resources</a> "	4.0.0-1 or later

## 3.2 Attributes common to group resources

A group is a failover unit. Rules regarding the failover operations (failover policies) can be specified for a group.

### 3.2.1 Understanding the group type

The following two types of groups exist: virtual machine groups and failover groups.

- **Virtual machine groups**

Failovers (migration) are performed on a virtual machine basis. The following resources can be registered with this group: virtual machine resource, mirror disk resource, disk resource, hybrid disk resource, EXEC resource, NAS resource, and volume manager resource. A virtual machine group automatically follows even when the virtual machine is moved to a different server by a means other than EXPRESSCLUSTER.

- **Failover groups**

Resources necessary to continue operations are grouped and failovers are performed on an operation basis. Up to 256 group resources can be registered with each group. However, no VM resource can be registered.

### 3.2.2 Understanding the group properties

The following properties can be specified for each group:

- **Servers that can run the Group**

Select a server that can run the group from the servers in the cluster.

Specify the order of servers that can run the group and the priority according to which the group is started.

- **Startup Attribute**

Specify automatic or manual startup as the group startup attribute.

For automatic startup, the group is automatically started on the server that can run the group and has the highest priority when the cluster is started.

For manual startup, the group is not started when the server is started. Manually start the group by using the Cluster WebUI or clpgrp command after the server is started. For details about the Cluster WebUI, see the online manual. For details about the clpgrp command, see "*Operating groups (clpgrp command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

- **Failover attribute**

The failover attribute can be used to specify the failover mode. The following failover attributes can be specified.

**Automatic failover**

A heartbeat timeout or error detection by a group or monitor resource triggers an automatic failover.

For an automatic failover, the following options can be specified.

- Use the startup server settings

The failover destination is determined according to the priority of the servers that can run the group.

- Fail over dynamically

The failover destination is determined by considering the statuses of each server's monitor resource or failover group, and then a failover is performed.

The failover destination is determined in the following way.

Determination factor	Condition	Result
Status of exclusion target monitor resource	Error (all servers)	When there is no failover destination, proceed to the processing for determining a forced failover judgment .
	Normal (single server)	A normal server is used as the failover destination.
	Normal (multiple servers)	Proceed to the process that compares error levels.
Perform a forced failover	Set	Proceed to the process that ignores the status of the exclusion target monitor resource and which compares error levels for all the activated servers.
	Not set	Failover is not performed.
Number of servers with the lowest error level	1	The server that has the lowest error level is used as the failover destination.
	Two or more	The operation levels are compared for those servers that have the lowest error level.
Prioritize failover policy in the server group	Set and Within the same server group as the failover source, there is a server that can perform failover.	The server in the same server group is used as the failover destination.
	Set and Within the same server group as the failover source, there is no server that can perform failover.	Proceed to the smart failover judgment process.
	Not set	Proceed to the smart failover judgment process.
Perform a smart failover	Set and The number of servers recommended as the failover destination is 1.	The server recommended by the smart failover is used as the failover destination.

Continued on next page

Table 3.4 – continued from previous page

Determination factor	Condition	Result
	Set and The number of servers recommended as the failover destination is 2 or more.	Proceed to the running level judgment process.
	Not set	Proceed to the running level judgment process.
Number of servers with the lowest running level	1	The server with the lowest running level is used as the failover destination.
	Two or more	Of the activated servers, the server with the highest priority is used as the failover destination.

**Note:****Critical monitor resource**

Exclude the server that detected an error in a monitor resource from the failover destination. The exclusive list is set with the Cluster WebUI.

**Error level**

Number of monitor resources that detected errors

**Smart failover**

A function that assigns the server with the smallest load as the failover destination, based on the system resource information collected by the System Resource Agent. To enable this function, a System Resource Agent license must be registered on all the servers set as the failover destination and the system monitor resources must be set as the monitor resource. For detail about the system monitor resources, see "*Understanding System monitor resources*" in "*4. Monitor resource details*" in this guide.

**Running level**

Number of started failover groups or number of failover groups that are being started, excluding management groups

- **Prioritize failover policy in the server group**  
If a server in the same server group can be used as the failover destination, this server is preferably used. The server that can run the failover group and has the highest priority among the running servers is used as the failover destination.  
If no server in the same server group can be used as the failover destination, a server in another server group is used as the failover destination.
- **Allow only a manual failover between server groups**  
This can be selected only when the above **Prioritize failover policy in the server group** is set.

An automatic failover is performed only if a server within the same server group is the destination.

If no servers in the same server group can be used as the failover destination, failing over to a server in another server group is not automatically performed.

To move the group to a server in another server group, use the Cluster WebUI or `clpgrp` command.

#### Manual failover

A failover is not automatically performed when a heartbeat timeout occurs. Manually start a failover by using the Cluster WebUI or `clpgrp` command. However, even when manual failover is specified, an automatic failover is performed if a group resource or monitor resource detects an error.

---

**Note:** If **Execute Failover to outside the Server Group** is set in message receive monitor resource setting, dynamic failover setting and failover setting between server groups will be invalid. A failover is applied to the server that is in a server group other than the server group to which the failover source server belongs and which has the highest priority.

---

- **Failback attribute**

Specify automatic or manual failback. However, This cannot be specified when the following conditions match.

- Mirror disk resource or hybrid disk resource is set to fail over group.
- Failover attribute is **Fail over dynamically**.

For automatic failback, an automatic failback is performed when the server that has the highest priority is started after a failover.

For manual failback, no failback occurs even when the server is started.

### 3.2.3 Understanding failover policy

A failover policy is a priority that determines a server to be the failover destination from multiple servers. When you configure the failover policy, avoid making certain servers heavily loaded at a failover.

The following describes how servers behave differently depending on failover policies when a failover occurs using example of the server list that can fail over and failover priority in the list.

<Symbols and meaning>

Server status	Description
 <b>Normal</b>	Normal (properly working as a cluster)
 <b>Stopped</b>	Stopped (cluster is stopped)

3-node configuration:

Group	Priority order of servers		
	1st priority server	2nd priority server	3rd priority server
A	Server 1	Server 3	Server 2
B	Server 2	Server 3	Server 1

2-node configuration:

Group	Priority order of servers	
	1st priority server	2nd priority server
A	Server 1	Server 2
B	Server 2	Server 1

It is assumed that the group startup attributes are set to auto startup and the failback attributes are set to manual failback for both Group A and B.

- For groups belonging to exclusion rules in which exclusive attributes are Normal or Absolute, the server which they start up or fail over is determined by the failover priority to the server. If a group has two or more servers of the same failover priority, it is determined by the order of numbers, the specific symbols and alphabets of the group name. For details on the failover exclusive attribute, refer to "*Understanding Exclusive Control of Group*".

**When Group A and B do not belong to the exclusion rules:**

Fig. 3.1: The status of each server, and the startup status of Groups A and B

1. Cluster startup
2. Cluster shutdown
3. Failure of Server 1 Fails over to the next priority server.
4. Server 1 power on
5. Cluster shutdown
6. Move group A
7. Failure of Server 2: Fails over to the next priority server.
8. Failure of Server 2: Fails over to the next priority server.
9. Failure of Server 3: Fails over to the next priority server.
10. Failure of Server 2: Fails over to the next priority server.
11. Failure of Server 3: Fails over to the next priority server.

When Group A and B belong to the exclusion rules in which the exclusive attribute is set to Normal:

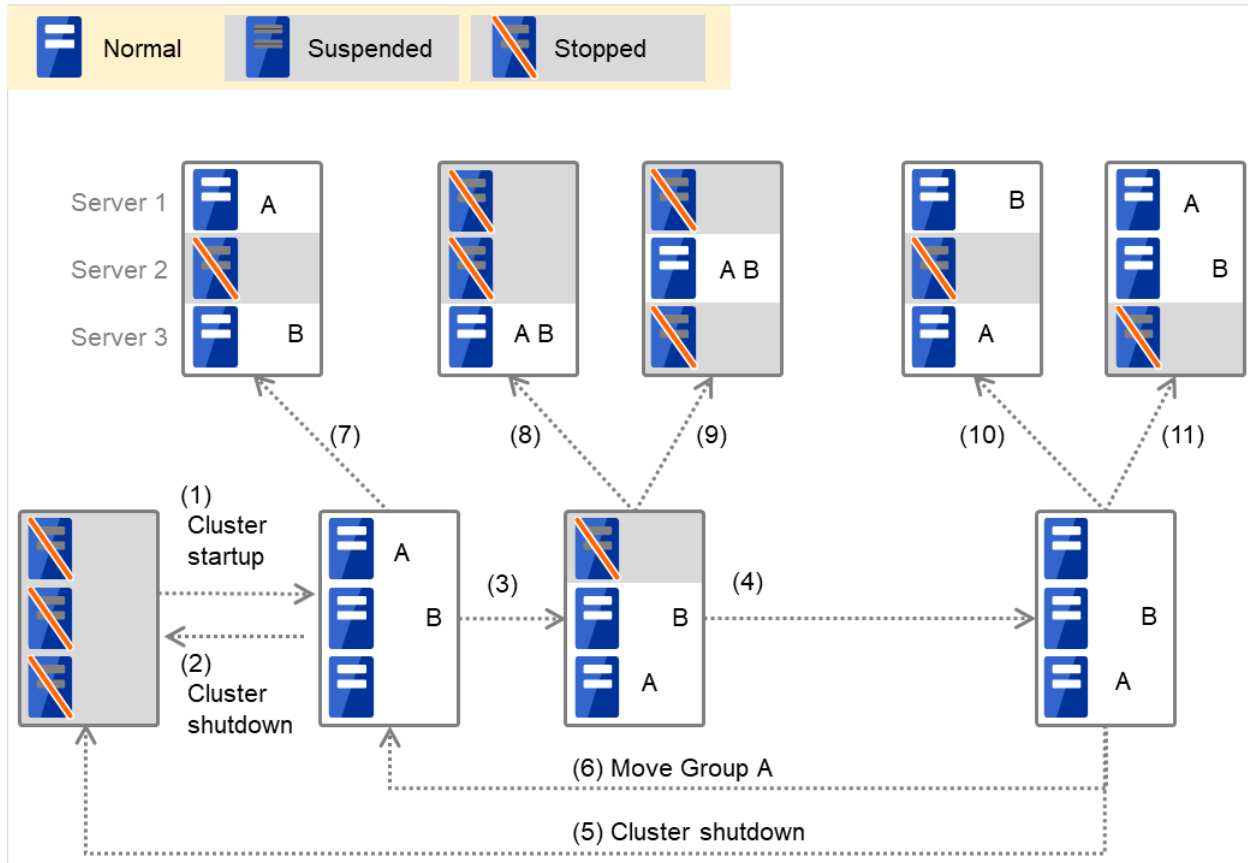

Fig. 3.2: The status of each server, and the startup status of Groups A and B (whose exclusive attributes are Normal)

1. Cluster startup
2. Cluster shutdown
3. Failure of Server 1: Fails over to a server where no normal exclusive group is active.
4. Server 1 power on
5. Cluster shutdown
6. Move Group A
7. Failure of Server 2: Fails over to a server where a normal exclusive group is not active.
8. Failure of Server 2: There is no server where a normal exclusive group is not active, but failover to the server because there is a server that can be started.
9. Failure of Server 3: There is no server where a normal exclusive group is not active, but failover to the server because there is a server that can be started.
10. Failure of Server 2: Fails over to a server where a normal exclusive group is not active.
11. Failure of Server 3: Fails over to a server where a normal exclusive group is not active.

When Group A and B belong to the exclusion rules in which the exclusive attribute is set to Absolute:

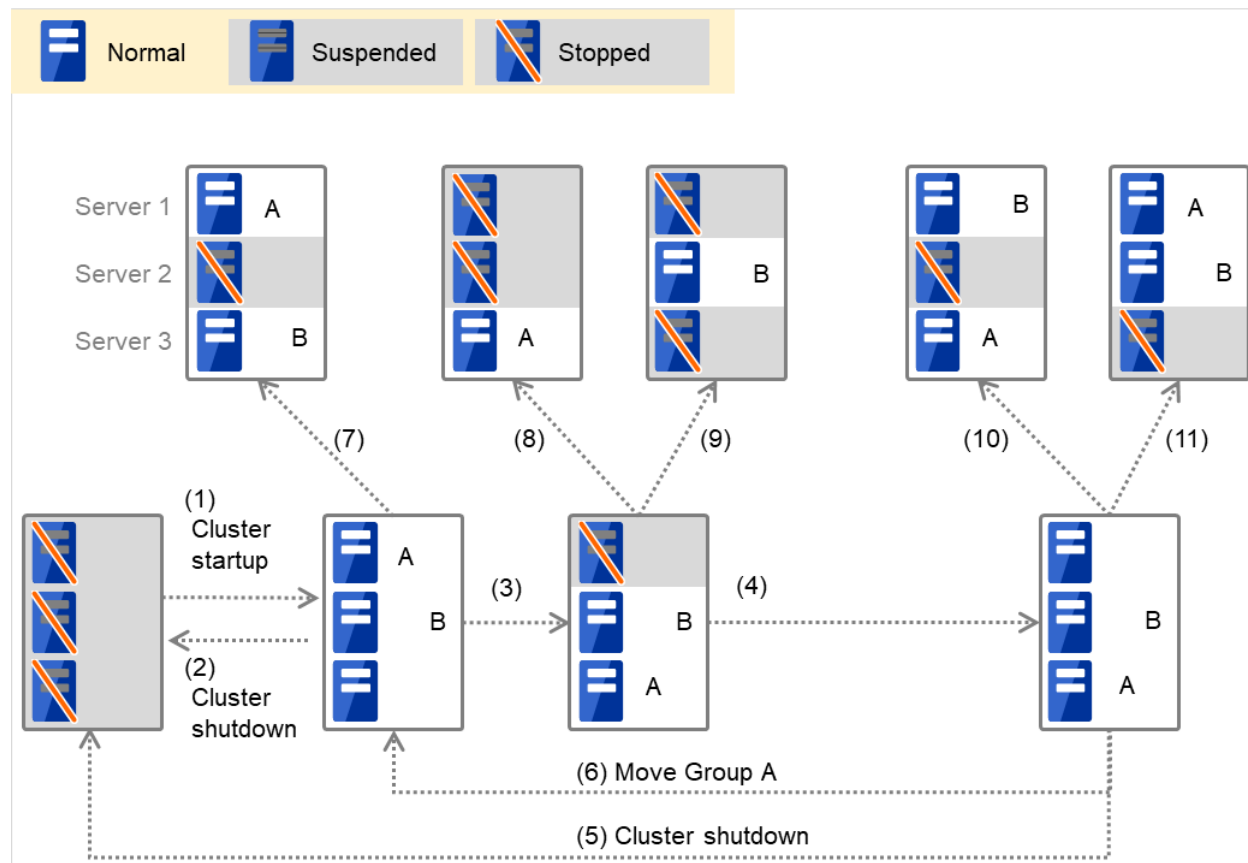

Fig. 3.3: The status of each server, and the startup status of Groups A and B (whose exclusive attributes are Absolute)

1. Cluster startup
2. Cluster shutdown
3. Failure of Server 1: Fails over to the next priority server.
4. Server 1 power on
5. Cluster shutdown
6. Move Group A
7. Failure of Server 2: Fails over to the next priority server.
8. Failure of Server 2: Does not failover (Group B stops).
9. Failure of Server 3: Does not failover (Group A stops).
10. Failure of Server 2: Fails over to the server where no absolute exclusive group is active.
11. Failure of Server 3: Fails over to the server where no absolute exclusive group is active.

**For Replicator (two-server configuration) When Group A and B do not belong to the exclusion rules:**

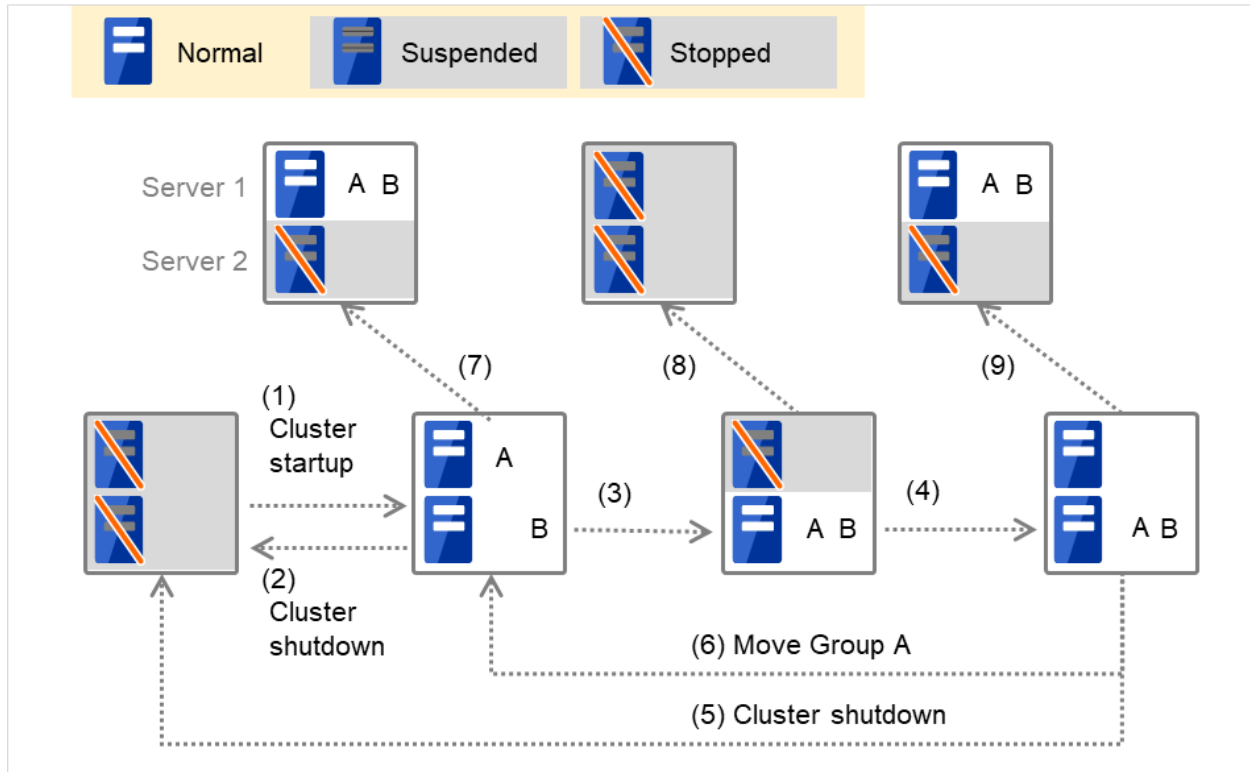

Fig. 3.4: The status of each server, and the startup status of Groups A and B (with Replicator)

1. Cluster startup
2. Cluster shutdown
3. Failure of Server 1: Fails over to the standby server of GroupA.
4. Server 1 power on
5. Cluster shutdown
6. Move Group A
7. Failure of Server 2: Fails over to the standby server of GroupB.
8. Failure of Server 2
9. Failure of Server 3: Fails over to the standby server.

### 3.2.4 Operations at detection of activation and deactivation failure

When an activation or deactivation error is detected, the following operations are performed:

- When an error in activation of group resources is detected:
  - When an error in activation of group resources is detected, activation is retried.
  - When activation retries fail as many times as the number set to **Retry Count at Activation Failure**, a failover takes place.
  - If the failover fails as many times as the number set to **Failover Threshold**, the final action is performed.
- When an error in deactivation of group resources is detected:
  - When an error in deactivation of group resources is detected, deactivation is retried.
  - When deactivation retries fail as many times as the number set to **Retry Count at Deactivation Failure**, the final action is performed.

---

#### Note:

Activation retries and failovers are counted on a server basis. The Retry Count at Activation Failure and Failover Threshold are maximum activation retry count and failover count on a server basis respectively.

The activation retry count and failover count are reset in a server where the group activation is successful.

Note that a failed recovery action is also counted as one for the activation retry count or failover count.

---

The following describes how an error in activation of a group resource is detected:

When the following settings are made:

Retry Count at Activation Failure 3 times

Failover Threshold 1 time

Final Action Stop Group

- (1) The following figure illustrates that Servers 1 and 2 are connected to the shared disk.  
With Failover group A on Server 1, Disk resource 1 will start to be activated (e.g. for mounting the file system).

Fig. 3.5: Flow of operation on detecting a group resource activation failure (1)

(2) The activation of Disk resource 1 fails due to an fsck error, a mount error, or other causes.

Fig. 3.6: Flow of operation on detecting a group resource activation failure (2)

(3) The activation of Disk resource 1 is retried up to three times (activation retry count).

Fig. 3.7: Flow of operation on detecting a group resource activation failure (3)

- (4) The failover of Failover group A is started.

**Failover Threshold** represents how many times failover is performed on each server.

So this is the first failover on Server 1.

Fig. 3.8: Flow of operation on detecting a group resource activation failure (4)

- (5) Disk resource 1 starts to be activated (e.g. for mounting the file system).

If a failure occurs on the way, the activation is retried up to three times.

Fig. 3.9: Flow of operation on detecting a group resource activation failure (5)

- (6) If the specified retry count is exceeded for the activation of Disk resource 1 on Server 2 as well, Failover group A starts to be failed over.  
This is the first failover on Server 2.

Fig. 3.10: Flow of operation on detecting a group resource activation failure (6)

- (7) On Server 1, the activation of Disk Resource 1 is started. If a failure occurs on the way, the activation is retried up to three times.

Fig. 3.11: Flow of operation on detecting a group resource activation failure (7)

- (8) If the specified retry count is exceeded for the activation of Disk resource 1 on Server 1 as well, the specified **Final Action** is started. No failover is performed then, because **Failover Threshold** is set at 1. **Final Action** means the action to be taken after the specified failover retry count is exceeded. Here, Failover group A starts to be stopped.

Fig. 3.12: Flow of operation on detecting a group resource activation failure (8)

### 3.2.5 Script before final action

When a group resource activation error is detected, a script before final action can be executed before the last action during detection of a deactivation error.

#### **Environment variables used with a script before final action**

When executing a script, EXPRESSCLUSTER sets information such as the state in which it is executed (when an activation error occurs, when a deactivation error occurs) in the environment variables.

In the script, processing that is appropriate for the system operation can be described using the environment variables listed below as branch conditions.

Environment variable	Value	Description
CLP_TIMING ...Execution timing	START	Executes a script before final action in the event of a group resource activation error.
	STOP	Executes a script before final action in the event of a group resource deactivation error.
CLP_GROUPNAME ...Group name	Group name	Indicates the name of the group containing the group resource in which an error that causes the script before final action to be executed is detected.
CLP_RESOURCENAME ...Group resource name	Group resource name	Indicates the name of the group resource in which an error that causes the script before final action to be executed is detected.

### Flow used to describe a script before final action

The following explains the environment variables in the previous topic and an actual script, associating them with each other.

### Example of a script before final action in the event of an activation error

```
#!/bin/sh

# *****
# *           preactaction.sh
# *****

ulimit -s unlimited
echo "START"

# Refer to the environment variable of the script execution factor to_
↪determine the subsequent process.
if [ "$CLP_TIMING" = "START" ]
then
    # Here, write a recovery process to be performed before the final action_
    ↪on an activation failure.
    #
else
    echo "NO_CLP"
fi

echo "EXIT"
exit 0
```

### Tips for creating a script before final action

Note the following when creating a script:

- If the script contains a command that will take some time to execute, always leave a trace that will indicate the completion of the execution of that command. If a problem occurs, you can use this information to isolate the failure. One way of leaving such a trace is to use `clplogcmd`.
- Method of describing in a script by using `clplogcmd`  
Using `clplogcmd`, you can output messages to the Alert logs of Cluster WebUI or syslog of the OS. For details on the `clplogcmd` command, see "*Outputting messages (clplogcmd command)*" in "8. EXPRESSCLUSTER

*command reference*" in this guide.

(Example: Script image)

```
clplogcmd -m "recoverystart.."
recoverystart
clplogcmd -m "OK"
```

### Notes on script before final action

- Stack size of the commands and application to be started from a script

A recovery script and a script before recovery action are executed with the stack size set to 2 MB. For this reason, if the commands and applications to be started from the script require a stack size of 2 MB or greater, a stack overflow will occur.

If a stack overflow occurs, set the stack size before starting the commands and applications.

- Condition that a script before final action is executed

A script before final action is executed before the final action upon detection of a group resource activation or deactivation failure. Even if **No operation (Next Resources Are Activated/Deactivated)** or **No operation (Next Resources Are Not Activated/Deactivated)** is set as the final action, a script before final action is executed.

If the final action is not executed because the maximum restart count has reached the upper limit or by the function to suppress the final action when all other servers are being stopped, a script before final action is not executed.

## 3.2.6 Script Before and After Activation/Deactivation

An arbitrary script can be executed before and after activation/deactivation of group resources.

### Environment variables used with a script after activation/deactivation

When executing a script, EXPRESSCLUSTER sets information such as the state in which it is executed (before activation, after activation, before deactivation, or after deactivation) in the environment variables.

Environment variable	Value	Description
CLP_TIMING ...Execution timing	PRESTART	Executes a script before a group resource is activated.
	POSTSTART	Executes a script after a group resource is activated.
	PRESTOP	Executes a script before a group resource is deactivated.
	POSTSTOP	Executes a script after a group resource is deactivated.

Continued on next page

Table 3.6 – continued from previous page

Environment variable	Value	Description
CLP_GROUPNAME ...Group name	Group name	Indicates the group name of the group resource containing the script.
CLP_RESOURCENAME ...Group resource name	Group resource name	Indicates the name of the group resource containing the script.

**Flow used to describe a script before and after activation/deactivation**

The following explains the environment variables in the previous topic and an actual script, associating them with each other.

**Example of a script before and after activation/deactivation**

```
#!/bin/sh
#*****
#                               rscentent.sh                               *
#*****
ulimit -s unlimited
echo "START"

if [ "$CLP_TIMING" = "PRESTART" ]
then
    echo "$CLP_GROUPNAME"
    echo "$CLP_RESOURCE_NAME"
    # Here, write any process to be performed before the resource activation.
    #

elif [ "$CLP_TIMING" = "POSTSTART" ]
then
    echo "$CLP_GROUPNAME"
    echo "$CLP_RESOURCE_NAME"
    # Here, write any process to be performed after the resource activation.
    #

elif [ "$CLP_TIMING" = "PRESTOP" ]
then
    echo "$CLP_GROUPNAME"
    echo "$CLP_RESOURCE_NAME"
    # Here, write any process to be performed before the resource_
    ↪deactivation.
    #

elif [ "$CLP_TIMING" = "POSTSTOP" ]
then
    echo "$CLP_GROUPNAME"
    echo "$CLP_RESOURCE_NAME"
    # Here, write any process to be performed after the resource_
    ↪deactivation.
    #

fi
echo "EXIT"
exit 0
```

**Tips for creating a script before and after activation/deactivation**

Note the following when creating a script:

- If the script contains a command that will take some time to execute, always leave a trace that will indicate the completion of the execution of that command. If a problem occurs, you can use this information to isolate the failure. One way of leaving such a trace is to use `clplogcmd`.
- Method of describing in a script by using `clplogcmd`  
Using `clplogcmd`, you can output messages to the Alert logs of Cluster WebUI or syslog of the OS. For details on the `clplogcmd` command, see "*Outputting messages (clplogcmd command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

(Example: Script image)

```
clplogcmd -m "start.."
:
clplogcmd -m "OK"
```

#### **Notes on script before and after activation/deactivation**

- Stack size of the commands and application to be started from a script  
A script before and after activation/deactivation is executed with the stack size set to 2 MB. For this reason, if the commands and applications to be started from the script require a stack size of 2 MB or greater, a stack overflow will occur.  
If a stack overflow occurs, set the stack size before starting the commands and applications.

### **3.2.7 Reboot count limit**

If the action which is accompanied by OS reboot is selected as the final action to be taken when any error in activation or deactivation is detected, you can limit the number of shutdowns or reboots caused by detection of activation or deactivation errors.

This maximum reboot count is the upper limit of reboot count of each server.

---

**Note:** The maximum reboot count is the upper limit of reboot count of a server because the number of reboots is recorded per server.

The number of reboots that are taken as a final action in detection of an error in group activation or deactivation and those by a monitor resource are recorded separately.

If the time to reset the maximum reboot count is set to zero (0), the number of reboots will not be reset. Run the clpregctrl command to reset this number. For details on the clpregctrl command, see "*Controlling reboot count (clpregctrl command)*" in "8. *EXPRESSCLUSTER command reference*".

---

The following describes the flow of operations when the limitation of reboot count is set as shown below:

As a final action, **Stop cluster daemon and reboot OS** is executed once because the maximum reboot count is set to one (1).

If group activation is successful at a reboot following the cluster shutdown, the reboot count is reset after 10 minutes because the time to reset maximum reboot count is set to 10 minutes.

#### **Setting example**

Retry Count at Activation Failure 0 time

Failover Threshold 0 time

Final Action Stop cluster service and reboot OS

Max Reboot Count 1 time

Max Reboot Count Reset Time 10 minutes

(1) The following figure illustrates that Servers 1 and 2 are connected to the shared disk.

With Failover group A on Server 1, Disk resource 1 will start to be activated (e.g. for mounting the file system).

Fig. 3.13: Process with the limited number of reboots (1)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	0	0

(2) The activation of Disk resource 1 fails due to an fsck error, a mount error, or other causes.

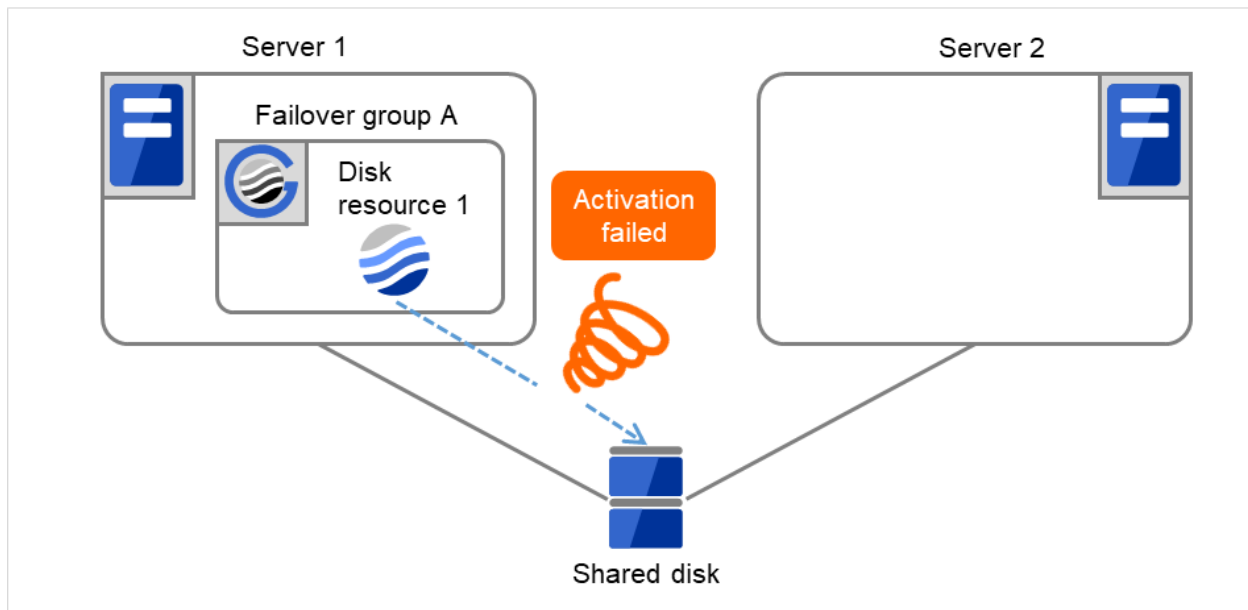

Fig. 3.14: Process with the limited number of reboots (2)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	0	0

- (3) Stop the cluster service, and then reboot the OS. Since both **Retry Count at Activation Failure** and **Failover Threshold** are set at zero (0), the final action is taken.  
On Server 1, the number of reboots is recorded as 1.

Fig. 3.15: Process with the limited number of reboots (3)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

- (4) The failover of Failover group A is started.

Fig. 3.16: Process with the limited number of reboots (4)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(5) Disk resource 1 starts to be activated (e.g. for mounting the file system).

The resource activation succeeds on Server 2, and the reboot is completed on Server 1.

Fig. 3.17: Process with the limited number of reboots (5)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(6) Start the failover of Failover group A by using the `clpgrp` command or Cluster WebUI.

Fig. 3.18: Process with the limited number of reboots (6)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(7) Disk resource 1 starts to be activated (e.g. for mounting the file system).

Fig. 3.19: Process with the limited number of reboots (7)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

- (8) The activation of Disk resource 1 fails due to an fsck error, a mount error, or other causes. The final action is not taken, because the reboot count has reached its maximum. Even after 10 minutes pass, the reboot count is not reset. An activation failure occurs in Failover Group A.

Fig. 3.20: Process with the limited number of reboots (8)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

- (9) Eliminate the disk error that caused the activation failure of Disk resource 1.  
After that, shut down the cluster by using the `clpstdn` command or Cluster WebUI. Then start the reboot.

Fig. 3.21: Process with the limited number of reboots (9)

Fig. 3.22: Process with the limited number of reboots (10)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(10) Starting up Failover group A succeeds.

After 10 minutes pass, the reboot count is reset.

Next time an activation failure occurs in Disk resource 1 during a startup of Failover group A, the final action will be taken.

Fig. 3.23: Process with the limited number of reboots (11)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

### 3.2.8 Resetting the reboot count

Run the `clpregctrl` command to reset the reboot count. For details on the `clpregctrl` command, see "*Controlling reboot count (clpregctrl command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

### 3.2.9 Checking a double activation

When a group is started, it is possible to check whether a double activation will occur or not.

- If a double activation is determined not to occur:  
A group startup begins.
- If a double activation is determined to occur (if a timeout occurs):  
A group startup does not begin. If the server attempts to start up the group, that group is stopped.

---

**Note:**

- If a single resource is started while its relevant group is stopped, a double activation check will be performed. However, if a single resource is started while any resource in the group is activated, a double activation check will not be performed.
- If there are no floating IP resources for the group for which **Execute Multi-Failover-Service Check** is selected, a double activation is not executed and the group startup begins.

- If a double activation is determined to occur, the statuses of groups and resources may not match among servers.

### 3.2.10 Understanding setting of group start dependence and group stop dependence

You can set the group start and stop order by setting group start dependence and group stop dependence.

- When group start dependence is set:
  - For group start, start processing of this group is performed after start processing of the group subject to start dependence completes normally.
  - For group start, if a timeout occurs in the group for which start dependence is set, the group does not start.
- When group stop dependence is set:
  - For group stop, stop processing of this group is performed after stop processing of the group subject to stop dependence completes normally.
  - If a timeout occurs in the group for which stop dependence is set, the group stop processing continues.
  - Stop dependence is performed according to the conditions specified in Cluster WebUI.

To display the settings made for group start dependence and group stop dependence, click group properties in the config mode of Cluster WebUI and then click the **Start Dependency** tab and the **Stop Dependency** tab.

Depths for group start dependence are listed below as an example.

Group Common Properties

Exclusion

Start Dependency

Stop Dependency

Start Dependency List

Depth	Name	Dependent Group Name
0	failover1	none
1	failover2	failover1
2	failover3	failover2

OK

Cancel

Apply

failover1

failover2

failover3

Fig. 3.24: Order of starting groups

The following explains group start execution using examples of simple status transition.

#### When two servers have three groups

#### Group failover policy

Group A Server 1  
Group B Server 2  
Group C Server 1 -> Server 2

**Group start dependence setting**

Group A Start dependence is not set.  
Group B Start dependence is not set.  
Group C Group A start dependence is set.  
Group C Start dependence is set when Group C is started by the server of Group B.

1. When Server 1 starts Group A and Group C

Server 1 starts Group C after Group A has been started normally.

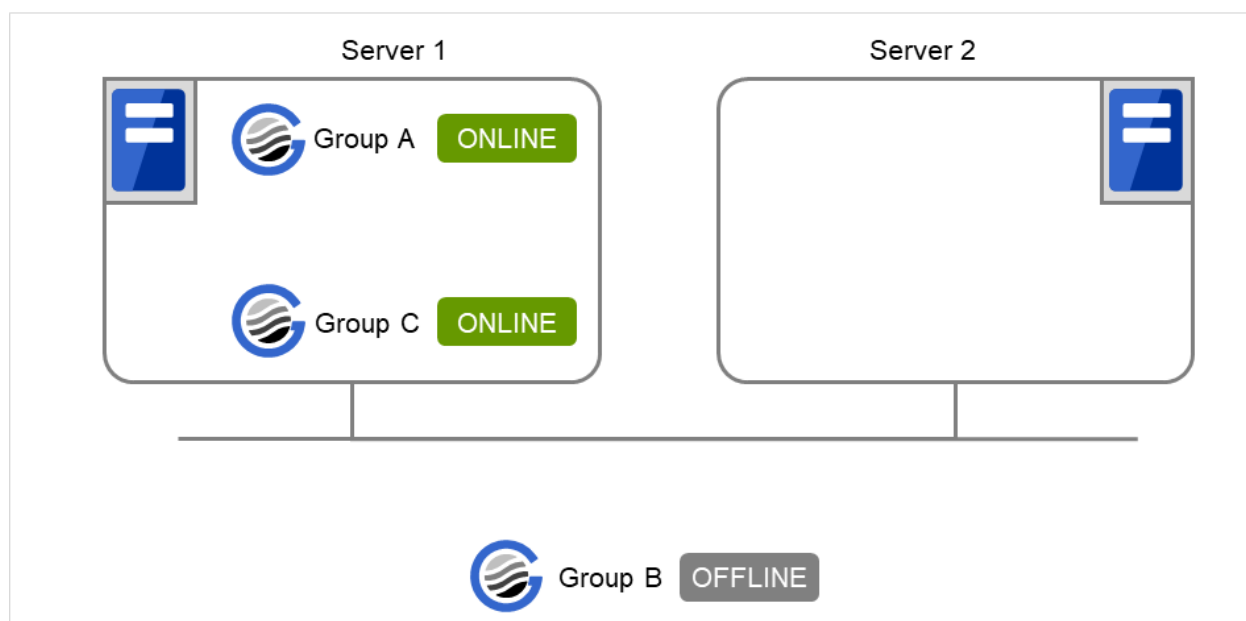

Fig. 3.25: Server 1 starts Group A and Group C

2. When Server 1 starts Group A and Server 2 starts Group C

Server 2 starts Group C after Server 1 has started Group A normally.

**Wait Only when on the Same Server** is not set, so Group A start dependence by another server is applied.

Fig. 3.26: Server 1 starts Group A and Server 2 starts Group C

### 3. When Server 1 starts Group C and Server 2 starts Group B

Server 1 starts Group C without waiting for the normal start of Group B. Group C is set to wait for Group B start only when it is started by the same server. However, start dependence is not applied to Group C because Group B is set such that it is not started by Server 1.

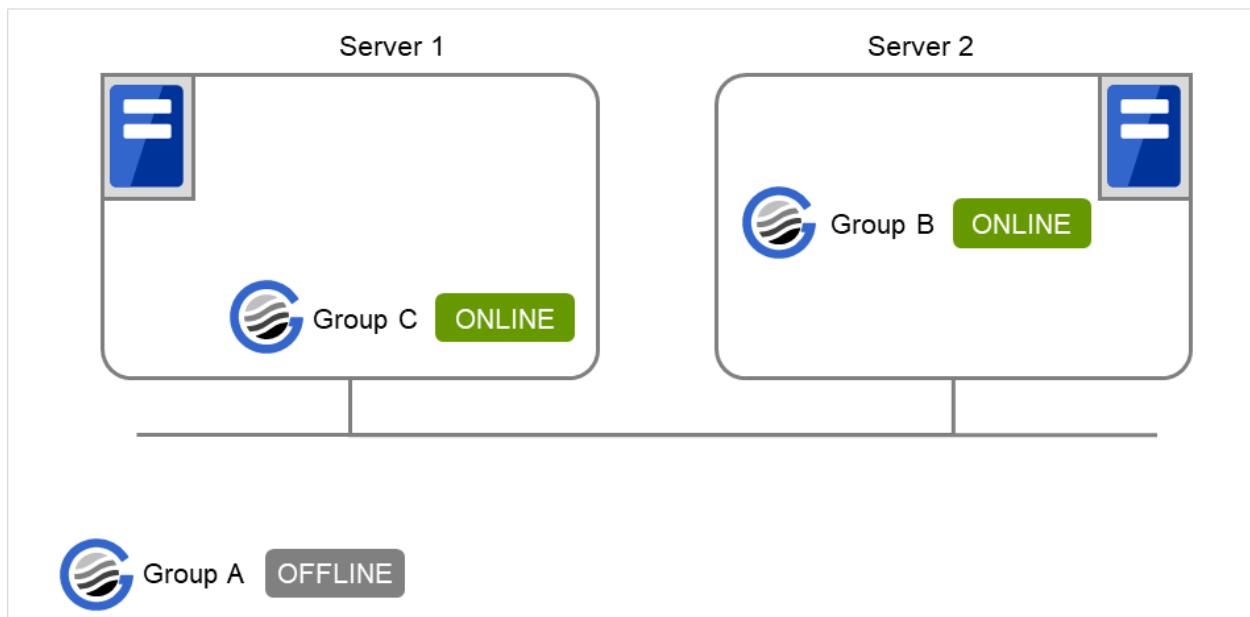

Fig. 3.27: Server 1 starts Group C and Server 2 starts Group B

### 4. When Server 1 starts Group A and Group C

If Server 1 fails in Group A start, Group C is not started.

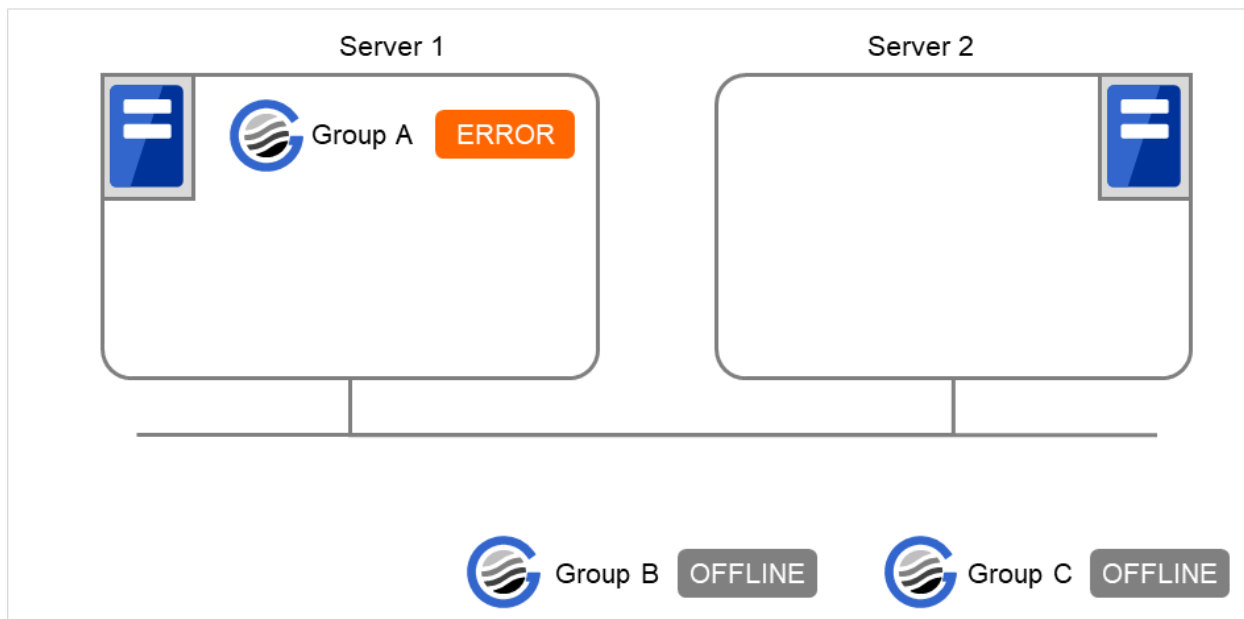

Fig. 3.28: Failing in starting Group A, Server 1 does not start Group C

5. When Server 1 starts Group A and Group C

If Server 1 fails in Group A start and a failover occurs in Server 2 due to Group A resource recovery, Server 2 starts Group A and then Server 1 starts Group C.

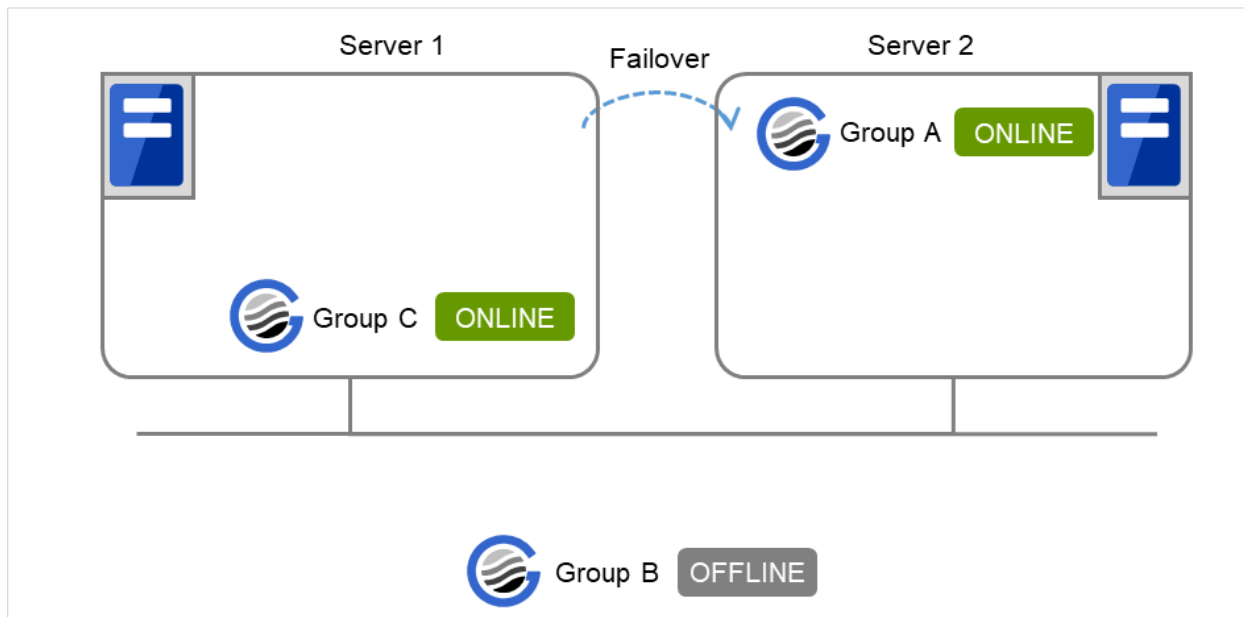

Fig. 3.29: GroupA fails over to Server 2, and Group C is started on Server 1

6. When Server 1 starts Group A and Group C

If a Group A start dependence timeout occurs on Server 1, Group C is not started.

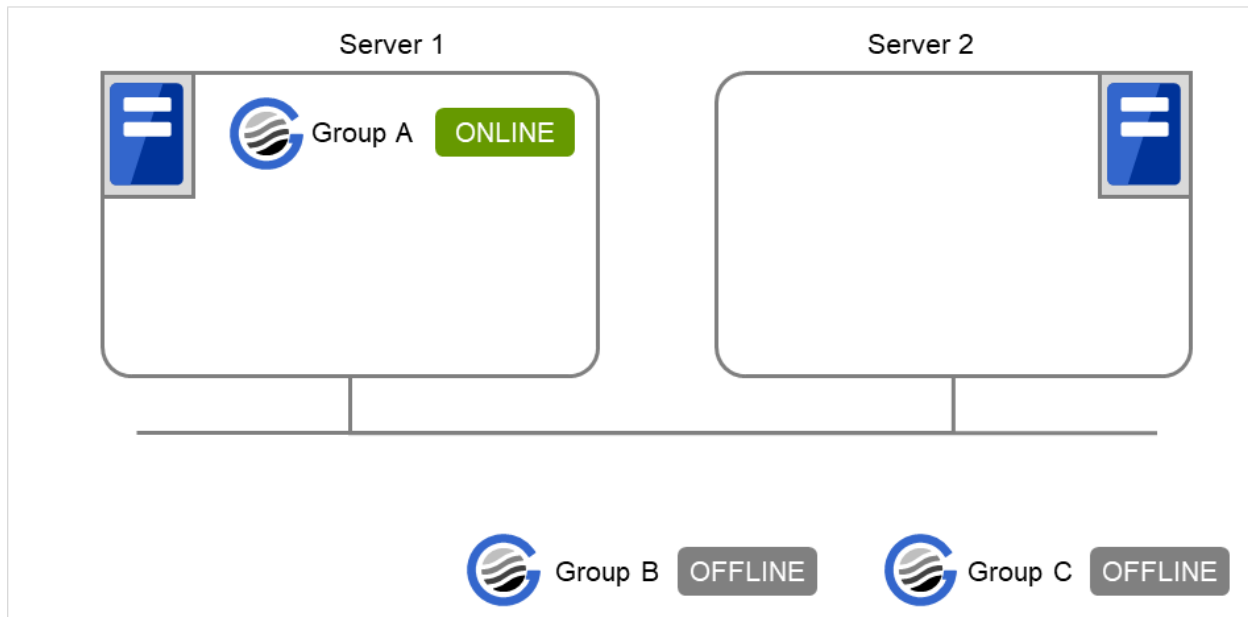

Fig. 3.30: Server 1 starts Group A

7. When Server 1 starts only Group C

Server 1 has not started Group A, so a start dependence timeout occurs. If this timeout occurs, Group C is not started.

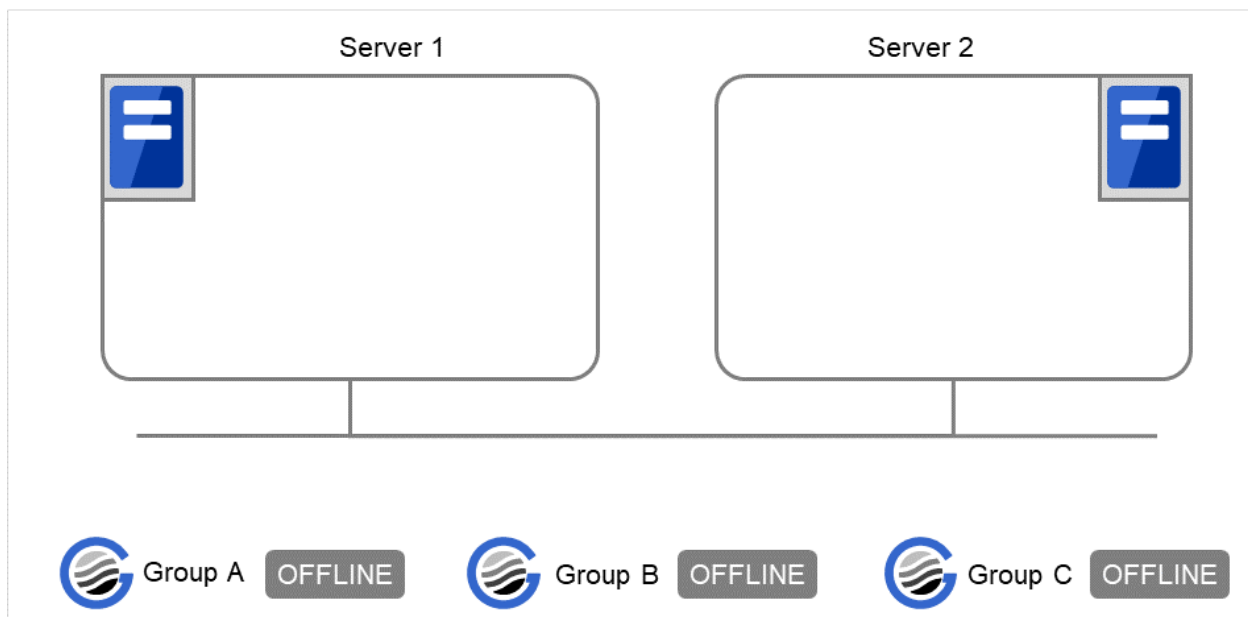

Fig. 3.31: Server 1 does not start Group A or Group C

---

**Note:**

- When a group is started, there is no function to automatically start the group for which start dependence is set.
  - The group is not started if a timeout occurs in the group for which start dependence is set.
  - The group is not started if the group for which start dependence is set fails to start.
  - If the group for which start dependence is set contains a normally started and a normally stopped resource, the group is judged to have started normally.
  - When a group is stopped, there is no function to automatically stop the group for which stop dependence is set.
  - The group stop processing continues if a timeout occurs in the group for which stop dependence is set.
  - The group stop processing continues if the group for which stop dependence is set fails to stop.
  - The group stop processing or resource stop processing by the Cluster WebUI or `clpgrp` command does not apply stop dependence. Stop dependence is applied according to the setting (when the cluster or a server stops) made with the Cluster WebUI.
  - If a start waiting timeout occurs at the time of a failover, the failover fails.
- 

### 3.2.11 Understanding Exclusive Control of Group

The Failover exclusive attributes set exclusive attributes of the group at failover. However, they cannot set any attribute under the following conditions:

- If **Virtual machine group** is specified as the group type
- When failover attribute is one of **Fail over dynamically**, **Prioritize failover policy in the server group** or **Enable only manual failover among the server groups**.

The settable failover exclusive attributes are as follows:

#### Off

Exclusion is not performed at failover. Failover is performed on the server of the highest priority among the servers that can fail over.

#### Normal

Exclusion is performed at failover. Failover is performed on the server on which the other normal exclusion groups are not started and which is given the highest priority among the servers that can run the group.

However, if the other normal exclusion groups have already been started on all servers that the failover can be performed, exclusion is not performed. Failover is performed on the server that is given the highest priority among the servers on which failover can be performed.

#### Absolute

Exclusion is performed at failover. Failover is performed on the server on which the other absolute exclusion groups are not started and which is given the highest priority among the servers that can run the group.

However, failover is not performed if the other absolute exclusion groups have already been started on all servers on which failover can be performed.

---

**Note:** Exclusion is not performed to the groups with different exclusion rules. Exclusive control is performed only among the groups with the same exclusion rule, according to the set exclusion attribute. In either case, exclusion is

not performed with the no-exclusion group. For details on the failover exclusive attribute, see "[Understanding failover policy](#)". Furthermore, For details on the settings of the exclusion rules, see "[Group common properties](#)".

### 3.2.12 Understanding server groups

This section explains about server groups.

Server groups are mainly groups of servers which are required when hybrid disk resources are used.

Upon using hybrid disk resources in a shared disk device, servers connected by the same shared disk device are configured as a server group.

Upon using hybrid disk resources in a disk which is not shared, a server is configured as a server group.

Of a server group, one (mirroring source/destination) server uses hybrid disk resources on a shared disk.

Fig. 3.32: Server groups

### 3.2.13 Understanding the settings of dependency among group resources

By specifying dependency among group resources, the order of activating them can be specified.

- When the dependency among group resources is set:
  - When activating a failover group that a group resource belongs to, its activation starts after the activation of the Dependent Resources is completed.
  - When deactivating a group resource, the deactivation of the "Dependent Resources" starts after the deactivation of the group resource is completed.

Depths for group start dependence are listed below as an example.

Group Properties | failover1

failover

Fig. 3.34: Example of a group resource deactivation order

### 3.2.14 Setting group resources for individual server

Some setting values of group resources can be configured for individual servers. On the properties of resources which can be set for individual servers, tabs for each server are displayed on the **Details** tab.

The following resources can be set for individual servers.

Group resource name	Supported version
Disk resource	4.0.0-1 or later
Floating IP resource	4.0.0-1 or later
Virtual IP resource	4.0.0-1 or later
Mirror disk resource	4.0.0-1 or later
Hybrid disk resource	4.0.0-1 or later
Dynamic DNS resource	4.0.0-1 or later
Virtual machine resource	4.0.0-1 or later
AWS Elastic IP resource	4.0.0-1 or later
AWS Virtual IP resource	4.0.0-1 or later
AWS DNS resource	4.0.0-1 or later
Azure DNS resource	4.0.0-1 or later

**Note:** Some parameters of Virtual IP resources, AWS Elastic IP resources, AWS Virtual IP resources, and Azure DNS resources should be configured for individual servers.

For parameters that can be set for individual servers, see the descriptions of parameters on each group resource. These parameters are marked with "Server Individual Setup".

In this example, the server individual setup for a Floating IP resource is explained.

Resource Properties | fip1

### Set Up Individually

Click the tab of the server on which you want to configure the server individual setting, and select this check box. The boxes for parameters that can be configured for individual servers become active. Enter required parameters.

**Note:** When setting up a server individually, you cannot select **Tuning**.

## 3.3 Group common properties

### 3.3.1 Exclusion tab

The dialog box titled "Group Common Properties" has a close button (X) in the top right corner. It features three tabs: "Exclusion" (selected), "Start Dependency", and "Stop Dependency". Below the tabs are four buttons: "Properties", "Rename", "Add", and "Remove". A section titled "Exclusive Rule List" contains a table with three columns: "Name", "Exclusive Attribute", and "Group". The table has one row with the values "excl1", "Normal Exclusion", and "failover1,failover2". At the bottom right are three buttons: "OK", "Cancel", and "Apply".

Name	Exclusive Attribute	Group
excl1	Normal Exclusion	failover1,failover2

#### Add

Add exclusion rules. Select **Add** to display the **Definition of Exclusion Rule** dialog box.

#### Remove

The confirmation dialog box is displayed.

#### Rename

The change server group name dialog box of the selected exclusion rule is displayed.

The dialog box titled "Rename exclusive rule | excl1" has a close button (X) in the top right corner. It contains a label "New name\*" followed by a text input field containing the text "excl1". At the bottom right are two buttons: "OK" and "Cancel".

There are the following naming rules.

- Up to 31 characters (31 bytes).
- Names cannot start or end with a hyphen (-) or a space.
- A name consisting of only numbers is not allowed.

Names should be unique (case-insensitive) in the exclusion rule.

#### Properties

Display the properties of the selected exclusion rule.

#### Definition of exclusion rule

The name of the exclusion rule and the exclusive attribute are set. Either **Normal** or **Absolute** can be set for an exclusive attribute. **Normal** can be set just one time, whereas **Absolute** can be set more than one time. If an exclusion rule in which **Normal** is set already exists, **Normal** cannot be set any more.

#### Name

Display the exclusion rule name.

### Exclusive Attribute

Display the exclusive attribute set in the exclusion rule.

### Group

Display the list of failover group names which belong to the exclusion rule.

The dialog box titled "Exclusive Rule Definition" contains the following fields and controls:

- Name\***: A text field containing "excl1".
- Comment**: An empty text field.
- Exclusive Attribute\***: A dropdown menu showing "Normal Exclusion".
- Exclusive Group**: A list box containing "failover1" and "failover2". "failover2" is selected and highlighted in light blue.
- Available Group**: A list box containing "failover3".
- Buttons**: "Add" (left arrow), "Remove" (right arrow), "OK", and "Cancel".

After selecting a group which you want to register into the exclusion rule from **Available Group**, press **Add**. **Exclusive Group** displays groups registered into the exclusion rule. A failover group added in another exclusion rule is not displayed on **Available Group**.

## 3.3.2 Start Dependency tab

Display the start dependency list.

The dialog box titled "Group Common Properties" has three tabs: "Exclusion", "Start Dependency" (selected), and "Stop Dependency".

**Start Dependency List**

Depth	Name	Dependent Group Name
0	failover1	none
1	failover2	failover1
2	failover3	failover2

Buttons: OK, Cancel, Apply

### 3.3.3 Stop Dependency tab

Display the stop dependency list.

The image shows a screenshot of the 'Group Common Properties' dialog box, specifically the 'Stop Dependency' tab. The dialog has a dark title bar with a close button. Below the title bar, there are three tabs: 'Exclusion', 'Start Dependency', and 'Stop Dependency', with the latter being the active tab. The main content area is titled 'Stop Dependency List' and contains a table with three columns: 'Depth', 'Name', and 'Dependent Group Name'. The table lists three entries: Depth 0 with Name 'failover3' and Dependent Group Name 'none'; Depth 1 with Name 'failover2' and Dependent Group Name 'failover3'; and Depth 2 with Name 'failover1' and Dependent Group Name 'failover2'. At the bottom right of the dialog, there are three buttons: 'OK', 'Cancel', and 'Apply'.

Depth	Name	Dependent Group Name
0	failover3	none
1	failover2	failover3
2	failover1	failover2

## 3.4 Group properties

### 3.4.1 Resources tab

The screenshot shows the 'Group Properties' dialog for 'failover1'. The 'Resources' tab is selected, displaying a table of resources. The table has five columns: Name, Type, Resource Startup Attribute, Retry Count, and Final Action. Three resources are listed: disk1 (Disk resource), exec1 (EXEC resource), and fip1 (Floating IP resource). All have 'Automatic startup' and 'No operation (not activate next resource)' as the final action. A scrollbar is visible at the bottom of the table. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

Name	Type	Resource Startup Attribute	Retry Count	Final Action
<a href="#">disk1</a>	Disk resource	Automatic startup	0 time	No operation (not activate next resource)
<a href="#">exec1</a>	EXEC resource	Automatic startup	0 time	No operation (not activate next resource)
<a href="#">fip1</a>	Floating IP resource	Automatic startup	5 time	No operation (not activate next resource)

Displays a list of group resources included in the selected group.

Clicking a name link takes you to the property screen of the corresponding resource.

### 3.4.2 Info tab

The screenshot shows the 'Group Properties' dialog for 'failover1' with the 'Info' tab selected. It contains fields for 'Type' (set to 'failover'), 'Use Server Group Settings' (unchecked checkbox), 'Name' (set to 'failover1'), and 'Comment' (empty text area). 'OK', 'Cancel', and 'Apply' buttons are at the bottom right.

#### Type

The group type is displayed.

#### Use Server Group Settings

- When the check box is selected  
Server group settings are used.
- When not selected  
Server group settings are not used.

#### Name

The group name is displayed.

#### Comment (Within 127 bytes)

Enter a comment for group. Use only one-byte alphabets and numbers.

### 3.4.3 Startup Server tab

There are two types of settings for the server that starts up the group: starting up the group on all servers or on only the specified servers and server groups that can run the group.

If the setting on which the group is started up by all the servers is configured, all the servers in a cluster can start a group. The group startup priority of servers is same as the one of servers. For details on the server priority, see "*Master server tab*" in "*Server Common Properties*" in "*2. Parameter details*" in this guide.

When selecting servers and server groups that can run the group, you can select any server or server group from those registered to the cluster. You can also change the startup priority of servers and server groups that can run the group.

**To set the server to start up the failover group:**

Group Properties | failover1 failover ✕

Info Startup Server Attribute Start Dependency Stop Dependency Entire Dependency

Failover is possible at all servers ☐

Servers that can run the Group

Order	Server
1	server1
2	server2

Available Servers

Server
server3

OK Cancel Apply

#### Failover is possible on all servers

Specify the server that starts a group.

- When the check box is selected:  
All servers registered to a cluster can start a group. The priority of starting up a group is same as the one of the servers.
- When not selected:  
You can select the servers that can start a group, and change the startup priority.

#### Add

Use this button to add a server. Select a server that you want to add from **Available Servers**, and then click **Add**. The server is added to **Servers that can run the Group**.

#### Remove

Use this button to remove a server. Select a server that you want to remove from **Servers that can run the Group**, and then click **Remove**. The server is added to **Available Servers**.

#### Order

Use these buttons to change the priority of the servers that can be started. Select a server whose priority you want to change from **Servers that can run the Group**. Click **the arrows** to move the selected row upward or downward.

#### To use the server group settings:

It is necessary to configure a server group that starts up the failover group for the settings of a server that starts up a group including a hybrid disk resource.

Group Properties | failover1 failover X

Info Startup Server Attribute Start Dependency Stop Dependency Entire Dependency

Server Groups that can run the Group

Order	Server group

↑ ↓

OK Cancel Apply

#### Add

Use **Add** to add a server group to **Server Groups that can run the Group**. Select a server group that you want to add from **Available Server Groups**, and then click **Add**. The selected server group is added to **Server Groups that can run the Group**.

#### Remove

Use **Remove** to remove a server group from **Server Groups that can run the Group**. Select a server group that you want to remove from **Available Server Groups**, and then click **Remove**. The server is added to **Server Groups that can run the Group**.

#### Order

Use these buttons to change the priority of a server group. Select a server group whose priority you want to change from **Server Groups that can run the Group**. Click **the arrows** to move the selected row upward or downward.

### 3.4.4 Attribute tab

Group Properties | failover1

failover X

Info Startup Server **Attribute** Start Dependency Stop Dependency Entire Dependency

**Startup Attribute** ☒ Automatic startup ☐ Manual Startup

**Execute Multi-Failover-Service Check** ☐

**Timeout** 300 sec

**Failover Attribute** ☒ Automatic failover

☒ Use startable server settings

☐ Failover dynamically

Edit exclusion monitor

☐ Perform a Forced Failover

☐ Prioritize failover policy in the server group

☐ Perform a Smart Failover

☐ Prioritize server group failover policy

☐ Enable only manual failover among the server groups

☐ Manual failover

**Failback Attribute** ☐ Automatic failback ☒ Manual failback

OK Cancel Apply

#### Startup Attribute

Select whether to automatically start the group from EXPRESSCLUSTER (auto startup), or to manually start from the Cluster WebUI or by using the clpgrp command (manual startup) at the cluster startup.

- Auto Startup  
The group will automatically be started at the cluster startup (active state).
- Manual Startup  
The group will not be started at the cluster startup (inactive state).  
You can start the group from the Cluster WebUI or by using the clpgrp command (active state).

#### Execute Multi-Failover-Service Check

Check whether a double activation will occur or not before a group is started.

#### Timeout (1 to 9999)

Specify the maximum time to be taken to check a double activation. The default value is set as 300 seconds. Specify a larger value than the one set for **Ping Timeout** of **Floating IP Resource Tuning Properties** for the floating IP resource that belongs to the group.

#### Failover Attribute

Select if the failover is automatically performed when a server fails.

- Auto Failover  
Failover is executed automatically. In addition, the following options can be selected.
  - Use the startup server settings  
This is the default setting.
  - Fail over dynamically

The failover destination is determined by considering the statuses of each server's monitor or failover group at the time of the failover.

If this option button is selected, all the failback attribute parameters are reverted to the default values and grayed out.

If dynamic failover is selected, each option can be set. For details, see "*Understanding the group properties*".

- Prioritize failover policy in the server group

This function controls failovers between sites (between server groups).

However, if no server group is specified for the failover group, the display for failovers between sites is grayed out.

The **Enable only manual failover among the server groups** check box can be selected only when this option button is selected.

If the **Prioritize failover policy in the server group** option button is selected, the failover policies in the same server group take priority when determining the failover destination.

If the **Prioritize failover policy in the server group** option button and **Enable only manual failover among the server groups** check box are selected, failovers across server groups are not automatically performed. Manually move groups between server groups.

- Manual Failover

Failover is executed manually.

#### Failback Attribute

Select if the failback is executed automatically to the group when a server that has a higher priority than other server where the group is active is started. For groups that have mirror disk resources or hybrid disk resources, select manual failback.

- Auto Failback

Failback is executed automatically.

- Manual Failback

Failback is not executed automatically.

#### Edit exclusive monitor

Dynamic failover excludes the server for which the monitor resource has detected an error, from the failover destinations. If **Fail over dynamically** is selected as the failover attribute, you can set the monitor resource to be excluded.

The exclusive list can be set with the monitor resource type and monitor resource name.

**Edit exclusion monitor** [X]

Exclude monitor resource type

[Add] [Remove]

**Monitor resource type**

---

IP monitor

---

NIC Link Up/Down monitor

Exclude monitor resource groups

[Edit] [Add] [Remove]

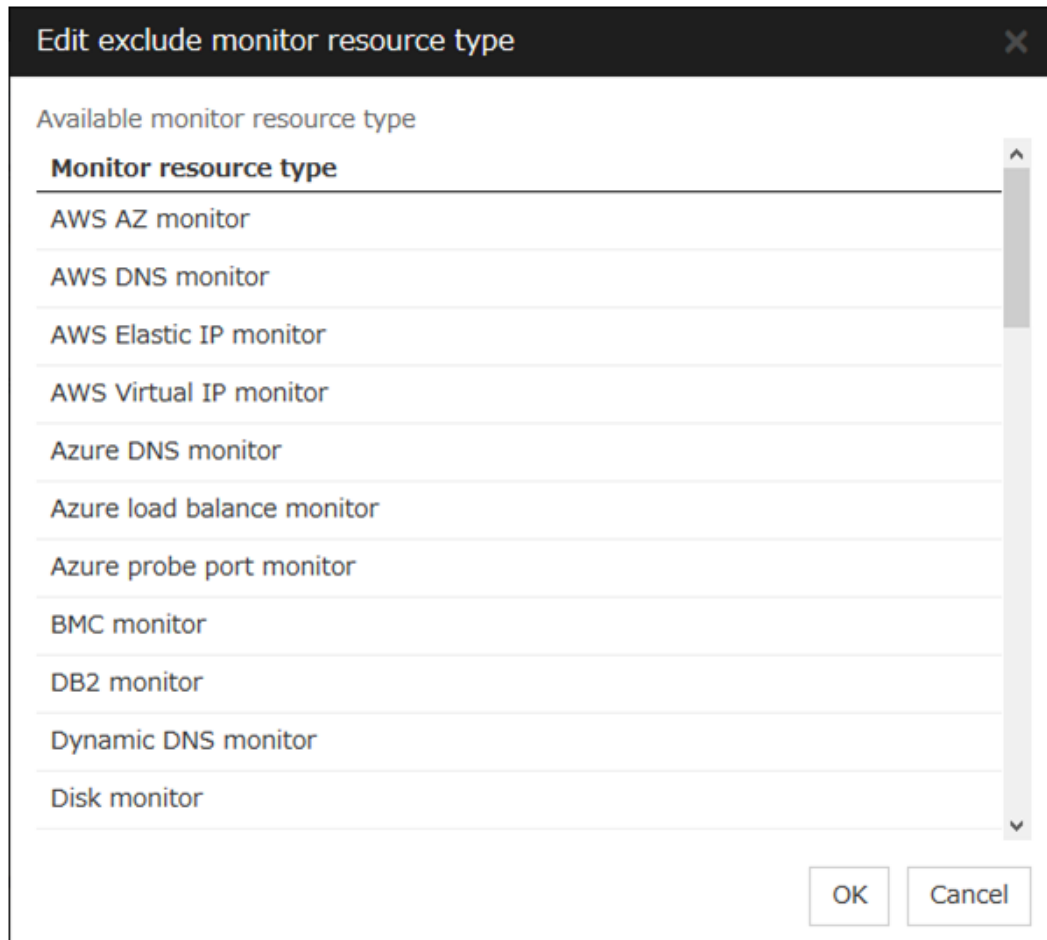

**No            Monitor resource group**

---

No Monitor resource group

[OK] [Cancel]

- **Add exclusive monitor resource type**  
Adds the exclusive monitor resource type.  
Any server, in which even one monitor resource of the added monitor resource type is abnormal, is excluded from the failover destinations.

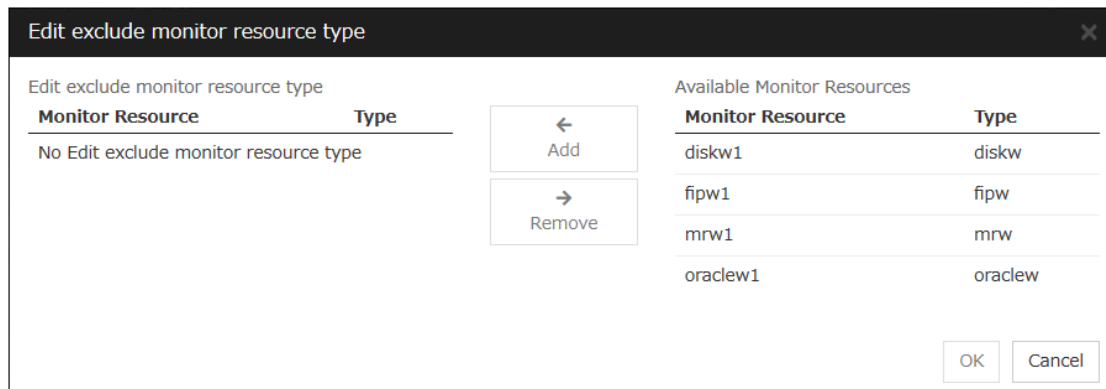

Adds the selected monitor resource type.

- Remove exclusive monitor resource type  
Removes the selected exclusive monitor resource type.
- Add exclusive monitor resource group  
Adds the exclusive monitor resource group.

The maximum number of exclusive monitor resource groups to be registered is 32.

If multiple monitor resources are registered in a single exclusive monitor resource group, the server in which all the registered monitor resources are abnormal is excluded from the failover destinations.

Moreover, if multiple exclusive monitor resource groups are registered, a server that satisfies at least one of the conditions is excluded from the failover destinations.

### Add

Adds the monitor resource selected from **Available monitor resource list** to **Monitor resource list**.

### Remove

Removes the monitor resource selected with **Monitor resource list**, from the list.

- Delete exclusive monitor resource group  
Removes the selected exclusive monitor resource group.
- Edit exclusive monitor resource group  
Edits the selected exclusive monitor resource group.

---

**Note:** The following monitor resource types cannot be registered for the exclusive monitor resource type. Moreover, a resource name cannot be registered for the exclusive monitor resource group.

- User mode monitor
  - ARP monitor
  - Virtual IP monitor
  - Mirror disk connect monitor
  - Hybrid disk monitor
  - Hybrid disk connect monitor
- 

### Note:

The monitor resource in the warning status is not handled as being abnormal. The exception to this is the mirror disk monitor resource.

The monitor resource set for monitoring at activation does not enter the abnormal status because it does not perform monitoring for a server other than the group start server.

The monitor resource stopped with the Cluster WebUI or clpmonctrl command enters the normal status. A server that has not been set to monitor a monitor resource does not enter the abnormal status because it does not perform monitoring.

---

**Note:**

In the case of the mirror disk monitor resource, a check is made as to whether the mirror disk resource can be activated. There is no dependence on the status of the mirror disk monitor resource.

Even if the mirror disk monitor resource is in the error status, the server on which the mirror disk resource can be activated normally is not excluded from the failover destination.

Even if the mirror disk monitor resource is in the normal or caution status, the server on which the mirror disk resource cannot be activated normally is excluded from the failover destination.

### 3.4.5 Start Dependency tab

The screenshot shows the 'Group Properties' dialog for 'failover1'. The 'Start Dependency' tab is selected. The 'Dependent Group' section is empty, showing 'No Dependent Groups'. The 'Available Group' section is also empty, showing 'No Available Groups'. There are 'Add' and 'Remove' buttons between the two sections. Below the 'Dependent Group' section, there is a 'Properties' button. At the bottom, there is a 'Start Wait Time\*' field with a value of '1800' and a unit of 'sec'. There are 'OK', 'Cancel', and 'Apply' buttons at the bottom right.

**Add**

Clicking **Add** adds the group selected from **Available Group** to **Dependent Group**.

**Remove**

Clicking **Remove** removes the group selected from **Dependent Group**.

**Start Wait Time (0 to 9999)**

Specify how many seconds you want to wait before a timeout in the target group start process. The default value is 1800 seconds.

**Property**

Clicking **Property** changes the properties of the group selected from **Dependent Group**.

The screenshot shows the 'failover2's Property' dialog. It has a single checkbox labeled 'Wait Only when on the Same Server' which is currently unchecked. There are 'OK' and 'Cancel' buttons at the bottom right.

### Wait Only when on the Same Server

Specify whether you wait for start waiting only when the group which starts waiting and the target group start on the same server.

- When **Wait Only when on the Same Server** is selected
  - When the server which starts the group that starts waiting isn't included in the Startup Server of a target group, you don't wait.
  - When a target group fails to start on a server other than the server which starts the group that starts waiting, you don't wait.

## 3.4.6 Stop Dependency tab

The screenshot shows the 'Group Properties' dialog for 'failover1'. The 'Stop Dependency' tab is selected. The 'Dependent Group' section is empty, showing 'No Dependent Groups'. The 'Available Group' section lists 'failover2' and 'failover3'. There are 'Add' and 'Remove' buttons between the sections. The 'Stop Wait Time' is set to 1800 seconds. Three checkboxes are present: 'Wait the Dependent Groups when a Cluster Stops' (checked), 'Wait the Dependent Groups when a Server Stops' (unchecked), and 'Wait the Dependent Groups when a Group Stops' (unchecked). 'OK', 'Cancel', and 'Apply' buttons are at the bottom right.

### Add

Clicking **Add** adds the group selected from **Available Group** to **Dependent Group**.

### Remove

Clicking **Remove** removes the group selected from **Dependent Group**.

### Stop Wait Time (0 to 9999)

Specify how many seconds to wait before a timeout occurs in the target group stop processing. The default value is 1800 seconds.

### Wait the Dependent Groups when a Cluster Stops

Specify whether to wait for the dependent groups to stop when the cluster stops.

### Wait the Dependent Groups when a Server Stops

Specify whether to wait for the dependent groups to stop when a single server stops. This option waits for the stop of only those groups running on the same server, among all the dependent groups.

### Wait the Dependent Groups when a Group Stops

Specify whether to wait for the dependent groups to stop when the groups are being stopped. This option waits for the stop of only those groups running on the same server, among all the dependent groups.

### 3.4.7 Entire Dependency tab

Displays the settings of dependency among group resources.

Group Properties | failover1 failover ✕

## 3.5 Resource Properties

### 3.5.1 Info tab

The screenshot shows a dialog box titled "Resource Properties | exec1" with a close button labeled "exec" and a small 'x' icon. The dialog has five tabs: "Info" (selected), "Dependency", "Recovery Operation", "Details", and "Extension". Under the "Info" tab, there are two labels: "Name" and "Comment". The "Name" label is followed by a text box containing the text "exec1". The "Comment" label is followed by an empty text box. At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Name

The resource name is displayed.

#### Comment (Within 127 bytes)

Enter a comment for the resource. Use only one-byte alphabets and numbers.

### 3.5.2 Dependency tab

Resource Properties | exec1

exec X

### Remove

It is used when removing the group resource selected in **Dependent Resources** from **Dependent Resources**.

## 3.5.3 Recovery Operation tab

### When an error in activation of the group resource is detected

- When an error is detected while activating the group resource, try activating it again.
- When the activation retry count exceeds the number of times set in **Retry Count at Activation Failure**, failover is executed.
- When the group resource cannot be activated even after executing a failover as many times as specified in **Failover Threshold**, the final action is taken.

### When an error in deactivation of the group resource is detected

- When an error is detected while deactivating the group resource, try deactivating it again.
- When the deactivation retry count exceeds the number of times set in **Retry Count at Deactivation Failure**, the final action is taken.

### Recovery Operation at Activation Failure Detection

#### Retry Count at Activation Failure (0 to 99)

Enter how many times to retry activation when an activation error is detected. If this is set to zero (0), the activation will not be retried.

#### Failover Threshold (0 to 99)

Enter how many times to retry failover after activation retry fails as many times as the number of times set in **Retry Count at Activation Failure** when an error in activation is detected.

If this is set to zero (0), failover will not be executed.

#### Final Action

Select an action to be taken when activation retry failed the number of times specified in **Activation Retry Threshold** and failover failed as many times as the number of times specified in **Failover Threshold** when an activation error is detected.

Select a final action from the following:

- No Operation (Activate next resource):  
Continues the group start process.
- No Operation (Not activate next resource):  
Cancels the group start process.
- Stop Group:  
Deactivates all resources in the group of which the group resource that an activation error is detected.
- Stop cluster service:  
Stops the cluster service of the server of which an activation error is detected.
- Stop cluster service and shutdown OS:  
Stops the cluster service of the server of which an activation error is detected, and shuts down the OS.

- Stop cluster service and reboot OS:  
Stops the cluster service of the server where an activation error is detected, and restarts the OS.
- Sysrq Panic:  
Performs the sysrq panic.

---

**Note:** If performing the sysrq panic fails, the OS is shut down.

---

- Keepalive Reset:  
Resets the OS using the clpkhb or clpka driver.

---

**Note:** If resetting keepalive fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported

---

- Keepalive Panic:  
Performs the OS panic using the clpkhb or clpka driver.

---

**Note:** If performing the keepalive panic fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported.

---

- BMC Reset:  
Perform hardware reset on the server by using the ipmi command.

---

**Note:** If resetting BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC Power Off:  
Powers off the OS by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If powering off BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC Power Cycle:  
Performs the power cycle (powering on/off) of the server by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If performing the power cycle of BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC NMI:  
Uses the ipmi command to cause NMI occur on the server. Actions after NMI occurrence depend on the OS settings.

---

**Note:** If BMC NMI fails, the OS shutdown is performed. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- I/O Fencing(High-End Server Option)  
It can't be used.

---

**Note:** If I/O Fencing(High-End Server Option) fails, the OS shutdown is performed.

---

### Execute Script before Final Action

Select whether script is run or not before executing final action when an activation failure is detected.

- When the check box is selected:  
A script/command is run before executing final action. To configure the script/command setting, click **Settings**.  
For the settings of the script, refer to the explanation about the script settings in "Execute Script before or after Activation or Deactivation".
- When the check box is not selected:  
Any script/command is not run.

### Recovery Operation at Deactivation Failure Detection

#### Retry Count at Deactivation Failure (0 to 99)

Enter how many times to retry deactivation when an error in deactivation is detected.

If you set this to zero (0), deactivation will not be retried.

#### Final Action

Select the action to be taken when deactivation retry failed the number of times specified in **Retry Count at Deactivation Failure** when an error in deactivation is detected.

Select the final action from the following:

- No Operation (Deactivate next resource):  
Continue the group stop process.

---

**Note:**

If **No Operation** is selected as the final action when a deactivation error is detected, group does not stop but remains in the deactivation error status.

Make sure not to set **No Operation** in the production environment.

---

- No Operation (Not deactivate next resource):  
Cancel the group start process.

---

**Note:**

If **No Operation** is selected as the final action when a deactivation error is detected, group does not stop but remains in the deactivation error status.

Make sure not to set **No Operation** in the production environment.

---

- Stop cluster service and shutdown OS:  
Stop the cluster daemon on the server of which error in deactivation is detected, and shut down the OS.
- Stop cluster service and reboot OS:

Stop the cluster daemon on the server where an error in deactivation is detected, and restart the OS.

- **Sysrq Panic:**  
Performs the sysrq panic.

---

**Note:** If performing the sysrq panic fails, the OS is shut down.

---

- **Keepalive Reset:**  
Resets the OS using the clpkhb or clpka driver.

---

**Note:** If resetting keepalive fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported

---

- **Keepalive Panic:**  
Performs the OS panic using the clpkhb or clpka driver.

---

**Note:** If performing the keepalive panic fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported.

---

- **BMC Reset:**  
Perform hardware reset on the server by using the ipmi command.

---

**Note:** If resetting BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- **BMC Power Off:**  
Powers off the OS by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If powering off BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- **BMC Power Cycle:**  
Performs the power cycle (powering on/off) of the server by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If performing the power cycle of BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- **BMC NMI:**  
Uses the ipmi command to cause NMI occur on the server. Actions after NMI occurrence depend on the OS settings.

---

**Note:** If BMC NMI fails, the OS shutdown is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- I/O Fencing(High-End Server Option):  
It can't be used.

---

**Note:** If I/O Fencing(High-End Server Option) fails, the OS shutdown is performed.

---

### Execute Script before Final Action

Select whether script is run or not before executing final action when a deactivation failure is detected.

- When the check box is selected:  
A script/command is run before executing final action. To configure the script/command setting, click **Settings**.  
For the settings of the script, refer to the explanation about the script settings in "Execute Script before or after Activation or Deactivation".
- When the check box is not selected:  
Any script/command is not run.

## 3.5.4 Details tab

The parameters specific to each resource are described in its explanation part.

## 3.5.5 Extension tab

The screenshot shows a window titled "Resource Properties | exec1" with a close button labeled "exec X". Inside the window, there are five tabs: "Info", "Dependency", "Recovery Operation", "Details", and "Extension". The "Extension" tab is currently selected. Under the "Extension" tab, there is a section titled "Resource Startup Attribute" with two radio buttons: "Automatic startup" (which is selected) and "Manual Startup". Below this, there is a section titled "Execute Script before or after Activation or Deactivation" with a "Settings" button. At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

### Resource Startup Attribute

Select whether to automatically start up the resource in starting up the group or manually (by using Cluster WebUI or the clprsc command).

### Execute Script before or after Activation or Deactivation

Select whether script is running or not before and after activation/deactivation of group resources. To configure the script settings, click Script Settings.

The image shows a 'Script Settings' dialog box. It has a dark header bar with the title 'Script Settings'. Below the header, there is a section titled 'Exec Timing' with a horizontal line underneath. Under this section, there are four unchecked checkboxes: 'Execute Script before Activation', 'Execute Script after Activation', 'Execute Script before Deactivation', and 'Execute Script after Deactivation'. At the bottom left of the dialog is a button labeled 'Settings', and at the bottom right is a button labeled 'Close'.

The script can be run at the specified timing by selecting the checkbox.

### Exec Timing

#### Execute Script before Activation

- Checkbox is on  
The script is executed before the resource is activated.
- Checkbox is off  
The script is not executed before the resource is activated.

#### Execute Script after Activation

- Checkbox is on  
The script is executed after the resources is activated.
- Checkbox is off  
The script is not executed after the resources is activated.

#### Execute Script before Deactivation

- Checkbox is on  
The script is executed before the resource is deactivated.
- Checkbox is off  
The script is not executed before the resource is deactivated.

#### Execute Script after Deactivation

- Checkbox is on  
The script is executed after the resource is deactivated.
- Checkbox is off  
The script is not executed after the resource is deactivated.

To configure the script settings, click Script Settings.

### User Application

Use an executable file (executable shell script file or execution file) on the server as a script. For the file name, specify an absolute path or name of the executable file of the local disk on the server. If there is any blank in the absolute path or the file name, put them in double quotation marks (") as follows.

Example:  
`"/tmp/user application/script.sh"`

Each executable files is not included in the cluster configuration information of the Cluster WebUI. They must be prepared on each server because they cannot be edited nor uploaded by the Cluster WebUI.

### Script created with this product

Use a script file which is prepared by the Cluster WebUI as a script. You can edit the script file with the Cluster WebUI if you need. The script file is included in the cluster configuration information.

#### File (Within 1023 bytes)

Specify a script to be executed (executable shell script file or execution file) when you select **User Application**.

#### View

Click here to display the script file when you select **Script created with this product**.

#### Edit

Click here to edit the script file when you select **Script created with this product**. Click **Save** to apply the change. You cannot modify the name of the script file.

#### Replace

Click here to replace the contents of a script file with the contents of the script file which you selected in the file selection dialog box when you select **Script created with this product**. You cannot replace the script file if it is currently displayed or edited. Select a script file only. Do not select binary files (applications), and so on.

#### Timeout (1 to 9999)

Specify the maximum time to wait for completion of script to be executed.

The default value of the time taken to execute script before and after activation/deactivation is 30 seconds.

The default value of the timeout settable from **Settings** button of **Execute Script before Final Action** for **Recovery Operation at Activation Failure Detection** or **Recovery Operation at Deactivation Failure Detection** is 5 seconds.

## 3.6 Understanding EXEC resources

You can register applications and shell scripts that are managed by EXPRESSCLUSTER and to be run when starting, stopping, failing over or moving groups in EXPRESSCLUSTER. It is also possible to register your own programs and shell scripts in EXEC resources. You can write codes as required for respective application because shell scripts are in the same format as an sh shell script.

---

**Note:** The same version of the application to be run from EXEC resources must be installed on all servers in failover policy.

---

### 3.6.1 Dependency of EXEC resources

By default, exec resources depend on the following group resource types:

Group resource type
Floating IP resource
Virtual IP resource
Disk resource
Mirror disk resource
Hybrid disk resource
NAS resource
VM resource
Volume manager resource
Dynamic DNS resource
AWS elastic ip resource
AWS virtual ip resource
AWS DNS resource
Azure probe port resource
Azure DNS resource

### 3.6.2 Method of judging EXEC resource activation/deactivation results

The activation/deactivation results are judged based on the results of executing the applications and shell scripts registered in the EXEC resources.

If the end code of an application or a shell script is 0, it is judged that activation/deactivation was performed normally and successfully.

If the end code is other than 0, it is judged that activation/deactivation has failed.

If a start/stop script timeout occurs, it is judged that activation/deactivation has failed.

### 3.6.3 Scripts in EXEC resources

#### Types of scripts

Start script and stop script are provided in EXEC resources. EXPRESSCLUSTER runs a script for each EXEC resource when the cluster needs to change its status. You have to write procedures in these scripts about how you want applications to be started, stopped, and restored in your cluster environment.

Fig. 3.35: Start script and stop script

Start: Start script  
Stop: Stop script

### 3.6.4 Environment variables in EXEC resource script

When EXPRESSCLUSTER runs a script, it records information such as condition when the scrip was run (script starting factor) in environment variables.

You can use the environment variables in the table below as branching condition when you write codes for your system operation.

Stop script returns the contents of the previous start script in the environment variable as a value. Start script does not set environment variables of CLP\_FACTOR and CLP\_PID.

The environment variable CLP\_LASTACTION is set only when the environment variable CLP\_FACTOR is CLUSTERSHUTDOWN or SERVERSHUTDOWN.

Environment Variable	Value of environment variable	Meaning
CLP_EVENT ...script starting factor	START	The script was run: <ul style="list-style-type: none"> <li>• by starting a cluster;</li> <li>• by starting a group;</li> <li>• on the destination server by moving a group;</li> <li>• on the same server by restarting a group due to the detection of a monitor resource error; or</li> <li>• on the same server by restarting a group resource due to the detection of a monitor resource error.</li> </ul>
	FAILOVER	The script was run on the failover target server: <ul style="list-style-type: none"> <li>• by the failure of the server;</li> <li>• due to the detection of a monitor resource error; or</li> <li>• because activation of group resources failed.</li> </ul>
CLP_FACTOR ...group stopping factor	CLUSTERSHUTDOWN	The group was stopped by stopping the cluster.
	SERVERSHUTDOWN	The group was stopped by stopping the server.
	GROUPSTOP	The group was stopped by stopping the group.
	GROUPMOVE	The group was moved by moving the group.
	GROUPFAILOVER	The group failed over because an error was detected in monitor resource; or the group failed over because of activation failure in group resources.
	GROUPRESTART	The group was restarted because an error was detected in monitor resource.
	RESTART	The group resource was restarted because an error was detected in monitor resource.
CLP_LASTACTION ...process after cluster shutdown	REBOOT	In case of rebooting OS
	HALT	In case of halting OS
	NONE	No action was taken.

Continued on next page

Table 3.17 – continued from previous page

Environment Variable	Value of environment variable	Meaning
CLP_SERVER ...server where the script was run	HOME	The script was run on the primary server of the group.
	OTHER	The script was run on a server other than the primary server of the group.
CLP_DISK <sup>1</sup> ...partition connection information on shared or mirror disks	SUCCESS	There was no partition where connection had failed.
	FAILURE	There was one or more partition where connection had failed.
CLP_PRIORITY ... the order in failover policy of the server where the script is run	1 to the number of servers in the cluster	Represents the priority of the server where the script is run. This number starts from 1 (The smaller the number, the higher the server's priority). If CLP_PRIORITY is 1, it means that the script is run on the primary server.
CLP_GROUPNAME ...Group name	Group name	Represents the name of the group to which the script belongs.
CLP_RESOURCENAME ...Resource name	Resource name	Represents the name of the resource to which the script belongs.
CLP_PID ...Process ID	Process ID	Represents the process ID of start script when the property of start script is set to asynchronous. This environment variable is null when the start script is set to synchronous.
CLP_VERSION_FULL ...EXPRESSCLUSTER full version	EXPRESSCLUSTER full version	Represents the EXPRESSCLUSTER full version. (Example) 4.3.4-1
CLP_VERSION_MAJOR ...EXPRESSCLUSTER major version	EXPRESSCLUSTER major version	Represents the EXPRESSCLUSTER major version. (Example) 4

Continued on next page

Table 3.17 – continued from previous page

Environment Variable	Value of environment variable	Meaning
CLP_PATH ...EXPRESSCLUSTER installation path	EXPRESSCLUSTER install path	Represents the path where EXPRESSCLUSTER is installed. (Example) /opt/nec/clusterpro
CLP_OSNAME ...Server OS name	Server OS name	Represents the OS name of the server where the script was executed. (Example) 1. When the OS name could be acquired: Red Hat Enterprise Linux Server release 6.8 (Santiago) 2. When the OS name could not be acquired: Linux
CLP_OSVER ...Server OS version	Server OS version	Represents the OS version of the server where the script was executed. (Example) 1. When the OS version could be acquired: 6.8 2. When the OS version could not be acquired: Blank

If the script is executed on the standby server, with **Execute on standby server** of **Exec Resource Tuning Properties** enabled, the following information is recorded in environment variables:

Environment variable	Value of environment variable	Meaning
CLP_EVENT ...script starting factor	STANDBY	The script was run on the standby server.
CLP_SERVER ...server where the script was run	HOME	The script was run on the primary server of the group.
	OTHER	The script was run on a server other than the primary server of the group.

Continued on next page

<sup>1</sup> It is available for disk resource, mirror disk resource, hybrid disk resource, NAS resource and volume manager resource.

Table 3.18 – continued from previous page

Environment variable	Value of environment variable	Meaning
CLP_PRIORITY ... the order in failover policy of the server where the script is run	1 to the number of servers in the cluster	Represents the priority of the server where the script is run. This number starts from 1 (The smaller the number, the higher the server's priority). If CLP_PRIORITY is 1, it means that the script is run on the primary server.
CLP_GROUPNAME ...Group name	Group name	Represents the name of the group to which the script belongs.
CLP_RESOURCENAME ...Resource name	Resource name	Represents the name of the resource to which the script belongs.
CLP_VERSION_FULL ...Full version of EXPRESSCLUSTER	Full version of EXPRESS-CLUSTER	Represents the full version of EXPRESS-CLUSTER (e.g. 4.3.4-1 ).
CLP_VERSION_MAJOR ...Major version of EXPRESSCLUSTER	Major version of EXPRESS-CLUSTER	Represents the major version of EXPRESS-CLUSTER (e.g. 4).
CLP_PATH ...EXPRESSCLUSTER installation path	EXPRESSCLUSTER installation path	Represents the EXPRESSCLUSTER installation path (e.g. /opt/nec/clusterpro).
CLP_OSNAME ...Server OS name	Server OS name	Represents the OS name of the server where the script was executed. (Example) 1. When the OS name was acquired: Red Hat Enterprise Linux Server release 6.8 (Santiago) 2. When the OS name was not acquired: Linux

Continued on next page

Table 3.18 – continued from previous page

Environment variable	Value of environment variable	Meaning
CLP_OSVER ...Server OS version	Server OS version	Represents the OS version of the server where the script was executed. (Example) 1. When the OS version was acquired: 6.8 2. When the OS version was not acquired: Blank

### 3.6.5 Execution timing of EXEC resource script

This section describes the relationships between the execution timings of start and stop scripts and environment variables according to cluster status transition diagram.

- To simplify the explanations, 2-server cluster configuration is used as an example. See the supplements for the relations between possible execution timings and environment variables in 3 or more server configurations.
- In the diagram, servers illustrates the following statuses:

Server	Server status
 Normal	Normal (properly working as a cluster)
 Stopped	Stopped (cluster is stopped)

(Example) Group A is working on a normally running server.

- Each group is started on the top priority server among active servers.
- Three Group A, B and C are defined in the cluster, and they have their own failover policies as follows:

Group	1st priority server	2nd priority server
A	Server 1	Server 2
B	Server 2	Server 1
C	Server 1	Server 2

<Cluster status transition diagram>

This diagram illustrates a typical status transition of cluster.

Fig. 3.36: Example of cluster status transition: overview

Numbers 1. to 11. in the diagram correspond to descriptions as follows.

#### 1. Normal startup

Normal startup here means that the start script has been run properly on the primary server.

Each group is started on the server with the highest priority among the active servers.

Fig. 3.37: Situation and script execution: normal startup

Environment variables for Start

	Group A	Group B	Group C
CLP_EVENT	START	START	START
CLP_SERVER	HOME	HOME	HOME

## 2. Normal shutdown

Normal shutdown here means a cluster shutdown immediately after the start script corresponding to the stop script that was run by performing normal startup or by moving a group (online failback).

Fig. 3.38: Situation and script execution: normal shutdown

Environment variables for Stop

	Group A	Group B	Group C
CLP_EVENT	START	START	START
CLP_SERVER	HOME	HOME	HOME

### 3. Failover at Server 1 down

When the start scrip of a group which has Server 1 as its primary server, it is run on a lower priority server (Server 2) when an error occurs. You need to write `CLP_EVENT(=FAILOVER)` as a branching condition for triggering application startup and recovery processes (such as database rollback process) in the start script in advance.

For the process to be performed only on a server other than the primary server, specify `CLP_SERVER(=OTHER)` as a branching condition and describe the process in the script.

Fig. 3.39: Situation and script execution: failover due to server down

Environment variables for Start

	Group A	Group C
CLP_EVENT	FAILOVER	FAILOVER
CLP_SERVER	OTHER	OTHER

#### 4. Cluster shutdown after failover of Server 1

The stop scripts of the Group A and C are run on Server 2 where the groups fail over (the stop script of Group B is run by a normal shutdown).

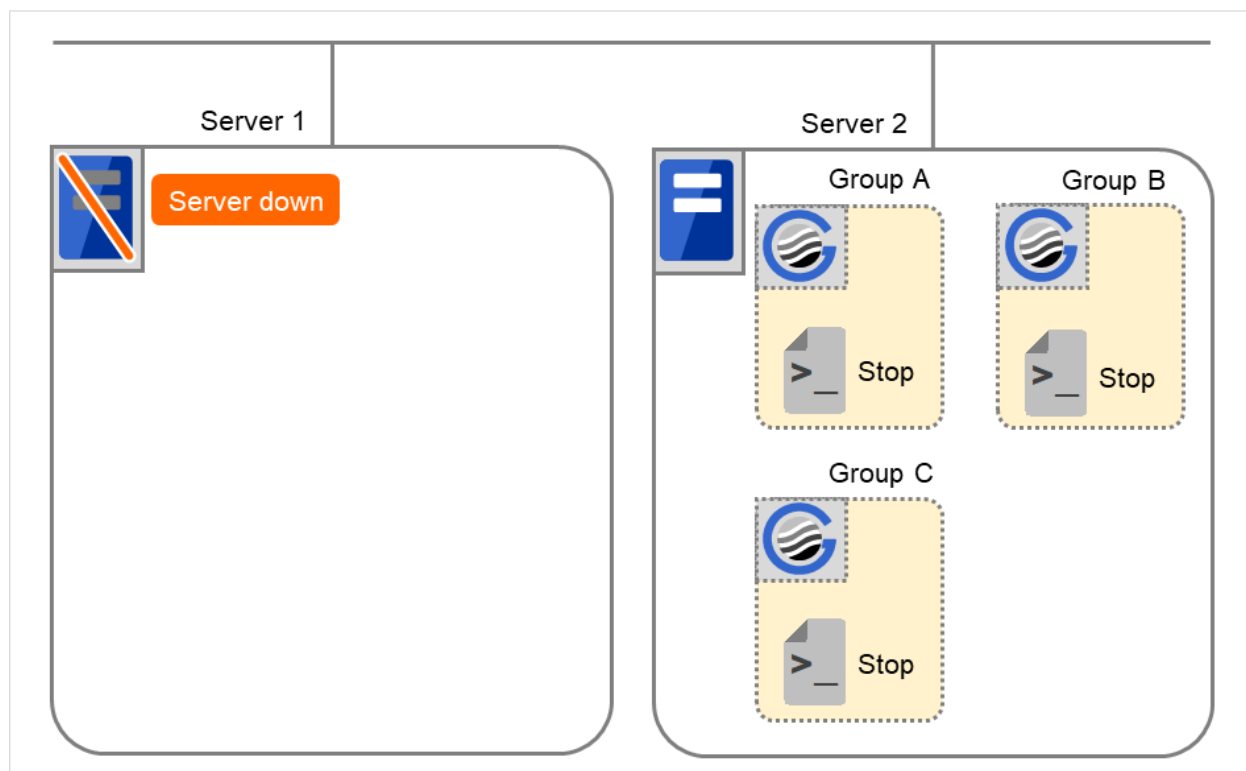

Fig. 3.40: Situation and script execution: cluster shutdown after failover

Environment variables for Stop

	Group A	Group B	Group C
CLP_EVENT	FAILOVER	START	FAILOVER
CLP_SERVER	OTHER	HOME	OTHER

## 5. Moving of Group A and C

After the stop scripts of Group A and C are run on Server 2 where the groups fail over, their start scripts are run on Server 1.

Fig. 3.41: Situation and script execution: moving Groups A and C (1)

Fig. 3.42: Situation and script execution: moving Groups A and C (2)

Environment variables for Stop

	Group A	Group C
CLP_EVENT	FAILOVER <sup>2</sup>	FAILOVER
CLP_SERVER	OTHER	OTHER

Environment variables for Start

	Group A	Group C
CLP_EVENT	START	START
CLP_SERVER	HOME	HOME

## 6. Error in Group C and failover

When an error occurs in Group C, its stop script is run on Server 1 and start script is run on Server 2.

Fig. 3.43: Situation and script execution: error in Group C and failover (1)

---

2

Environment variables in a stop script take those in the previous start script.

For moving in "5. Moving of Group A and C" because it is not preceded by a cluster shutdown, the environment variable used here is FAILOVER. However, if a cluster shutdown is executed before moving in "5. Moving of Group A and C," the environment variable is START.

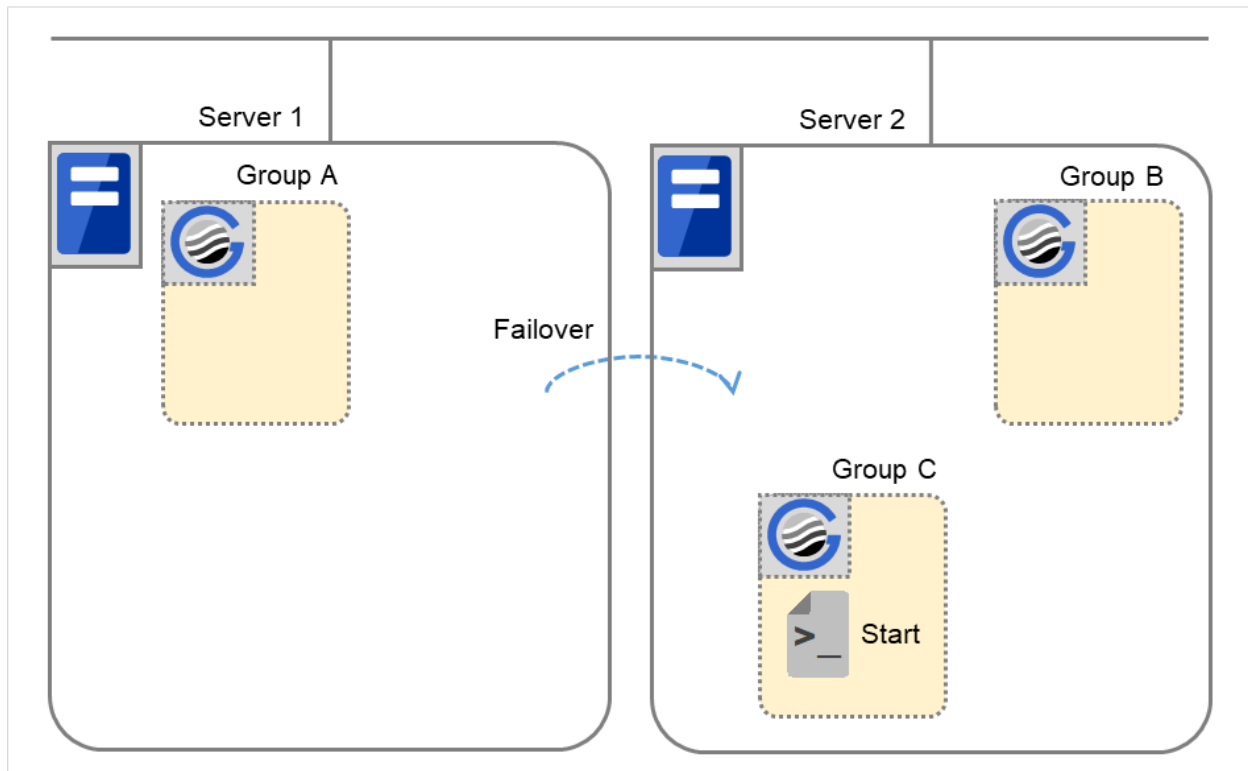

Fig. 3.44: Situation and script execution: error in Group C and failover (2)

Environment variables for Stop of Server 1

	Group C
CLP_EVENT	START
CLP_SERVER	HOME

Environment variables for Start of Server 2

	Group C
CLP_EVENT	FAILOVER
CLP_SERVER	OTHER

## 7. Moving of Group C

Move the Group C that is failed over to Server 2 in 6. from Server 2 to Server 1. Run the stop script on Server 2, and then run the start script on Server 1.

Fig. 3.45: Situation and script execution: moving Group C (1)

Stop (because this is failed over in 6.)

	Group C
CLP_EVENT	FAILOVER
CLP_SERVER	OTHER

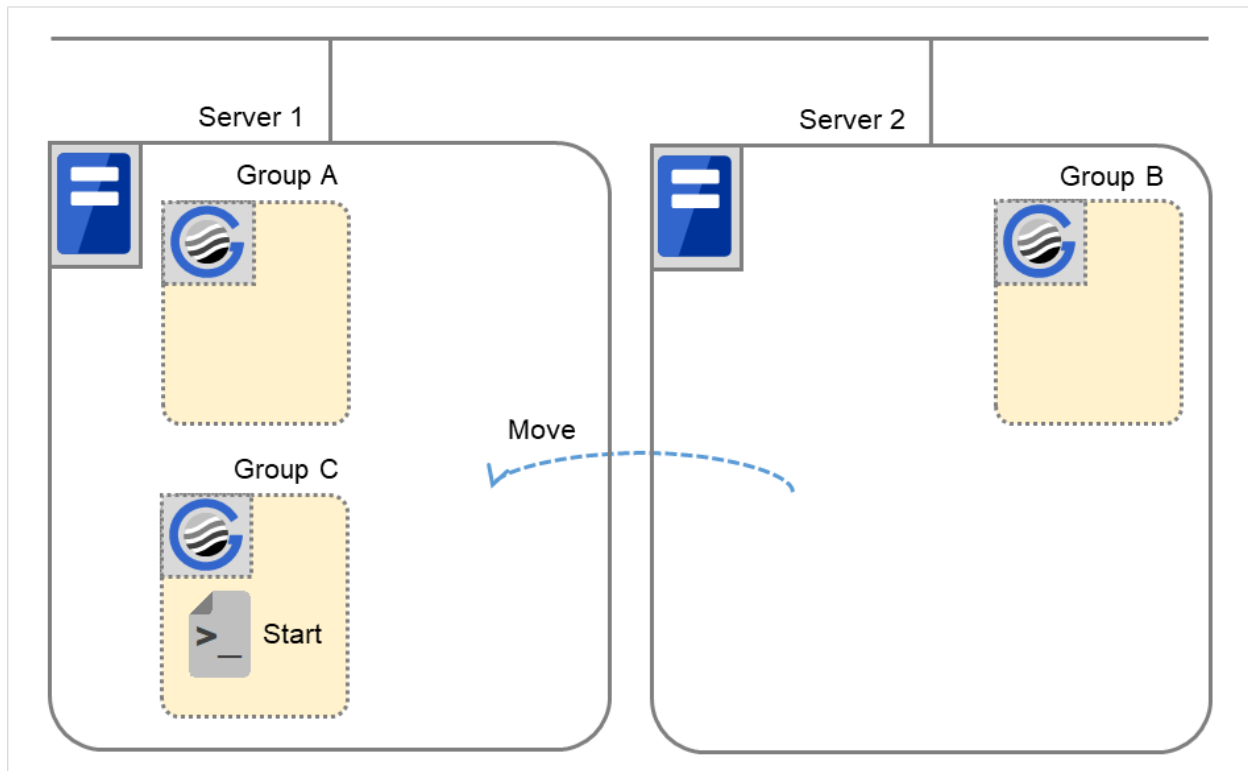

Fig. 3.46: Situation and script execution: moving Group C (2)

Start

	Group C
CLP_EVENT	START
CLP_SERVER	HOME

## 8. Stopping Group B

The stop script of Group B is run on Server 2.

Fig. 3.47: Situation and script execution: stopping Group B

Stop

	Group B
CLP_EVENT	START
CLP_SERVER	HOME

## 9. Starting Group B

The start script of Group B is run on Server 2.

Fig. 3.48: Situation and script execution: starting Group B

Start

	Group B
CLP_EVENT	START
CLP_SERVER	HOME

#### 10. Stopping Group C

The stop script of Group C is run on Server 2.

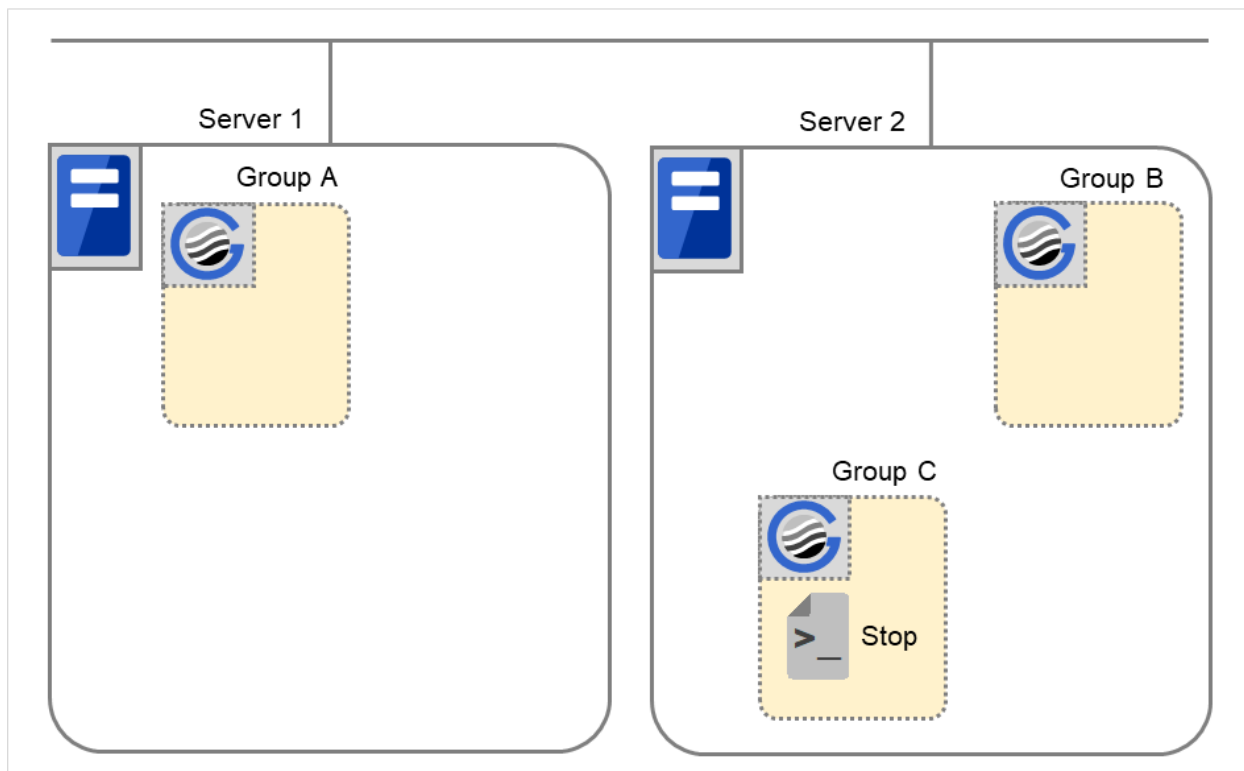

Fig. 3.49: Situation and script execution: stopping Group C

Stop

	Group C
CLP_EVENT	FAILOVER
CLP_SERVER	OTHER

#### 11. Starting Group C

The start scrip of Group C is run on Server 2.

Fig. 3.50: Situation and script execution: starting Group C

Start

	Group C
CLP_EVENT	START
CLP_SERVER	OTHER

#### Supplementary information 1

For a group that has three or more servers specified in the failover policy to behave differently on servers other than the primary server, use CLP\_PRIORITY instead of CLP\_SERVER(HOME/OTHER).

Fig. 3.51: Example of cluster status transition: failover due to server down

Example 1: "3. Failover at Server 1 down" in the cluster status transition diagram

A group has Server 1 as its primary server. If an error occurs on Server 1, its start script is run on Server 2 that has next highest priority failover policy. You need to write `CLP_EVENT(=FAILOVER)` as the branching condition for triggering applications' startup and recovery processes (such as database rollback process) in the start script in advance.

For a process to be performed only on the server that has the second highest priority failover policy, it is necessary to write `CLP_PRIORITY(=2)` as the branching condition.

Fig. 3.52: Situation and script execution: starting Groups A and C

Environment variables for Start

	Group A	Group C
CLP_EVENT	FAILOVER	FAILOVER
CLP_SERVER	OTHER	OTHER
CLP_PRIORITY	2	2

Example 2: "7. Moving of Group C" in the cluster status transition diagram

Fig. 3.53: Example of cluster status transition: moving Group C

After the stop script of Group C is run on Server 2 where the group failed over from, the start script is run on Server 3.

Fig. 3.54: Situation and script execution: moving Group C (1)

Environment variables for Stop

	Group C
CLP_EVENT	FAILOVER
CLP_SERVER	OTHER
CLP_PRIORITY	2

Fig. 3.55: Situation and script execution: moving Group C (2)

Environment variables for Start

	Group C
CLP_EVENT	START
CLP_SERVER	OTHER
CLP_PRIORITY	3

### Supplementary information 2

When monitor resource starts or restarts a script:

To run the start script when resource monitor detected an error in application, the environment variables should be as follows:

Example 1: Resource monitor detects abnormal termination of an application that was running on Server 1 and restarts Group A on the Server 1.

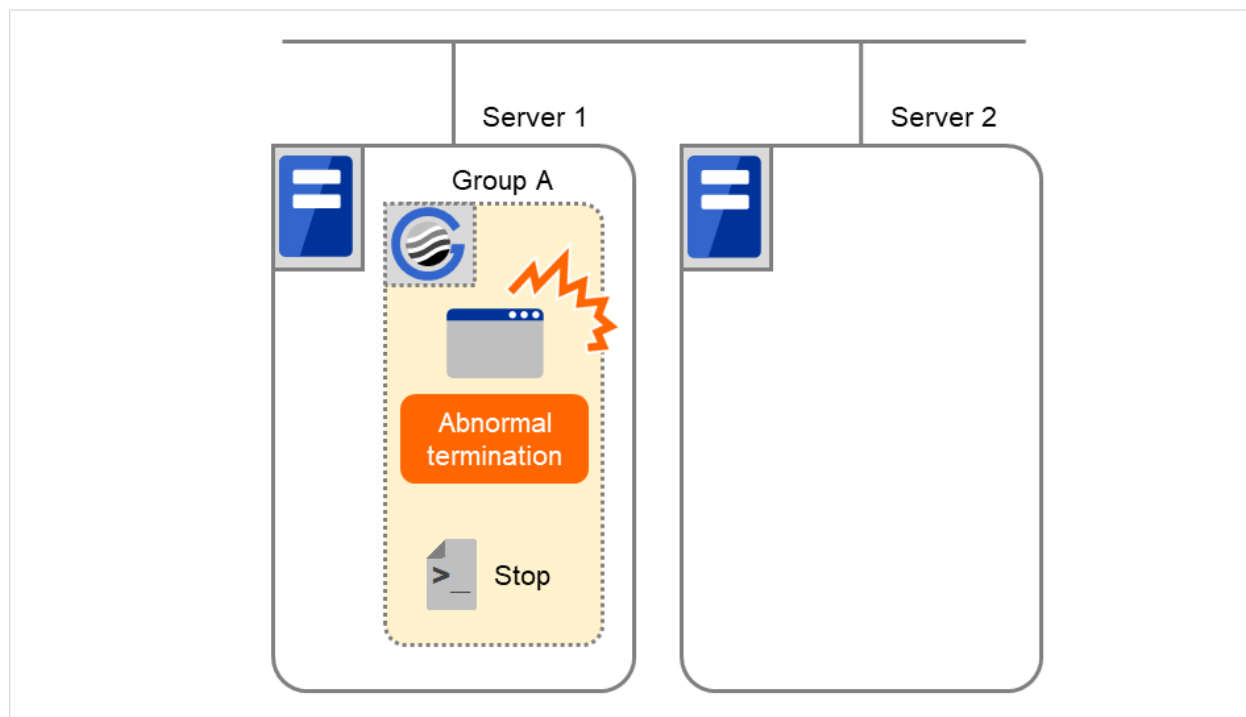

Fig. 3.56: Situation and script execution: restarting Group A (1)

Environment variable for Stop

	Group A
CLP_EVENT	The same value as when the start script is run

Fig. 3.57: Situation and script execution: restarting Group A (2)

Environment variable for Start

	Group A
CLP_EVENT	START

Example2: Resource monitor detects abnormal termination of an application that was running on Server 1, fails over to Server 2 and restarts Group A on Server 2

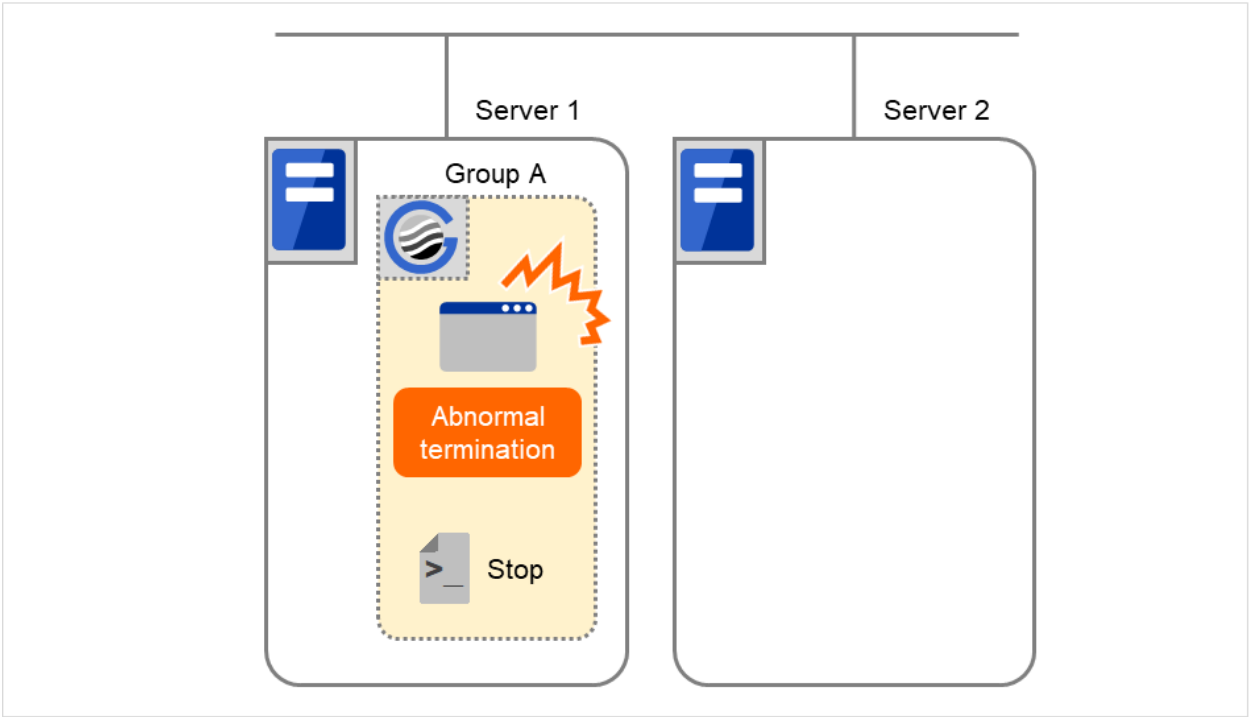

Fig. 3.58: Situation and script execution: failover of Group A (1)

Environment variable for Stop

	Group A
CLP_EVENT	The same value as when the start script is run

Fig. 3.59: Situation and script execution: failover of Group A (2)

Environment variable for Start

	Group A
CLP_EVENT	FAILOVER

### Supplementary information 3

With **Execute on standby server** of **Exec Resource Tuning Properties** enabled, start and stop scripts can also be executed on another server (standby server) that does not start a group--in accordance with the timings of running these scripts on the active server that started a group.

Compared with the script execution on the active server, that on the standby server has the following characteristics:

- The results (error codes) of executing the scripts do not affect the group-resource statuses.
- No script before and after activation/deactivation is executed.
- Monitor resources set for monitoring at activation are not started or stopped.
- Different types and values of environment variables are set. (Refer to "*Environment variables in EXEC resource script*" as described above.)

The following describes the relationships between the execution timings of scripts on the standby server and the environment variables--with cluster status transition diagrams.

<Cluster status transition diagram>

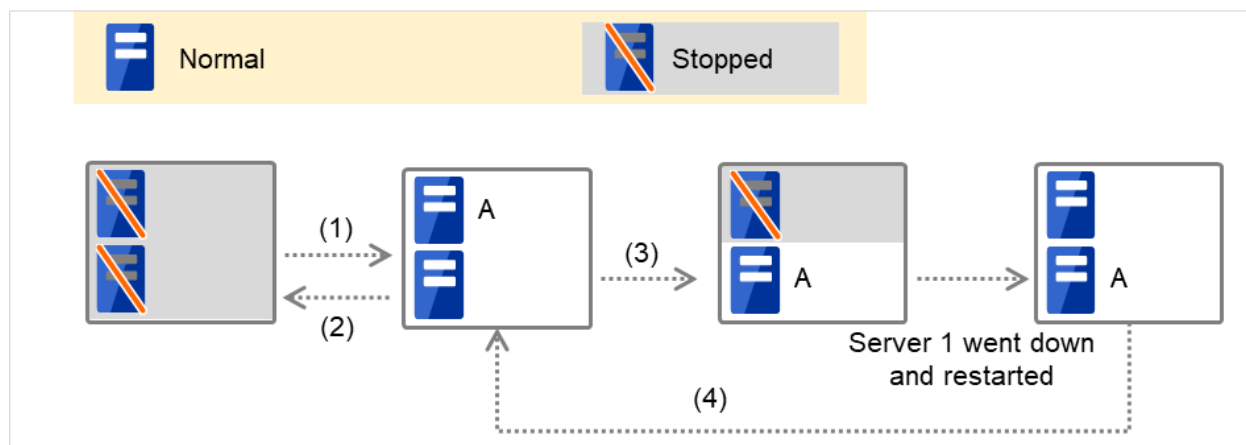

Fig. 3.60: Example of cluster status transition: failover due to server down

Numbers 1. to 4. in the diagram correspond to the following descriptions:

#### 1. Normal startup

For starting a group, the start script is run on the active server before executed on the standby server.

The start script requires a description, with CLP\_EVENT (= STANDBY) as a branch condition, of what to be done on the standby server.

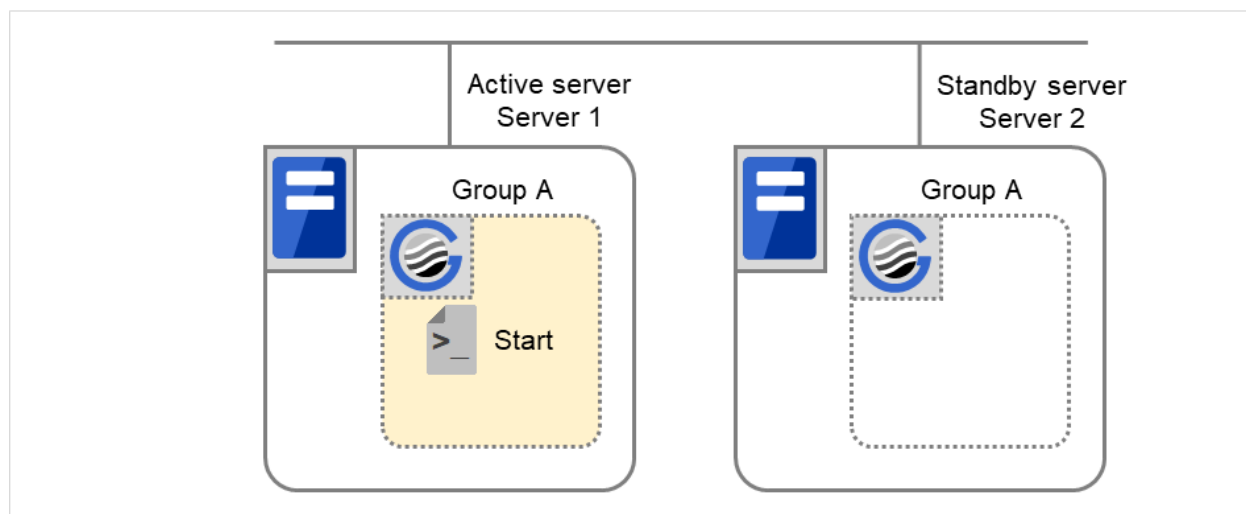

Fig. 3.61: Situation and script execution: normal startup of Group A (1)

Fig. 3.62: Situation and script execution: normal startup of Group A (2)

Environment variables for Start

	Server 1	Server 2
CLP_EVENT	START	STANDBY
CLP_SERVER	HOME	OTHER

## 2. Normal shutdown

For stopping a group, the stop script is run on the standby server before executed on the active server.

The stop script requires a description, with CLP\_EVENT (= STANDBY) as a branch condition, of what to be done on the standby server.

Fig. 3.63: Situation and script execution: normal shutdown of Group A (1)

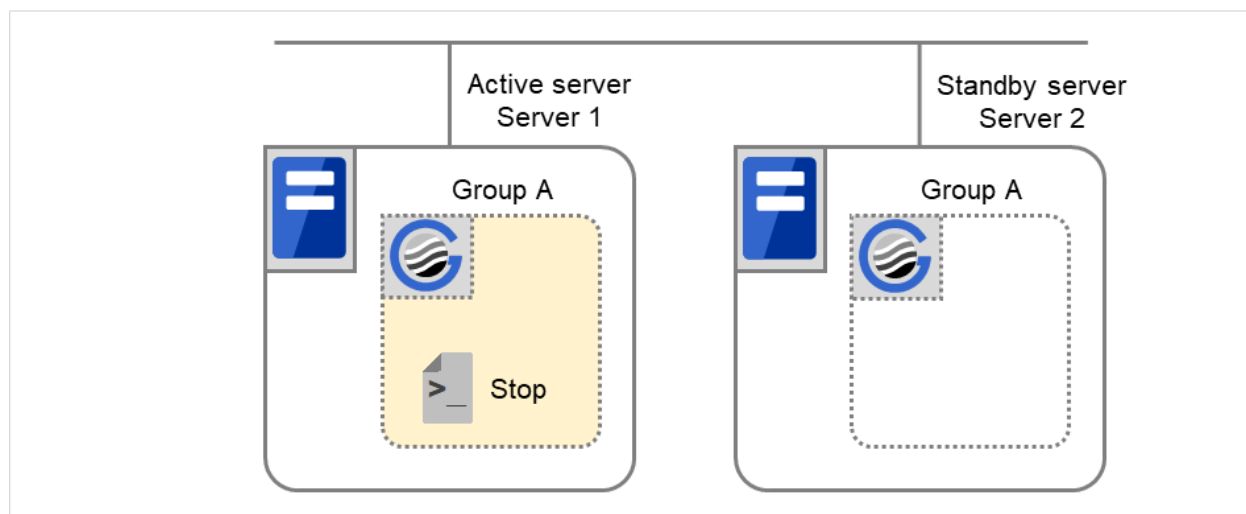

Fig. 3.64: Situation and script execution: normal shutdown of Group A (2)

Environment variables for Stop

	Server 1	Server 2
CLP_EVENT	START	STANDBY
CLP_SERVER	HOME	OTHER

### 3. Failover at Server 1 down

When an error occurs in Server 1, the group is failed over to Server 2, on which (as the active server) the start script is executed.

You need to write CLP\_EVENT (= FAILOVER) as a branch condition for triggering application startup and recovery processes (such as a database rollback process) in the start script in advance.

With Server 1 crashed, the start script is not run on it as the standby server.

Fig. 3.65: Example of cluster status transition: failover due to server down

Environment variables for Start

	Server 2
CLP_EVENT	FAILOVER
CLP_SERVER	OTHER

#### 4. Moving of Group A

The stop script for Group A is executed on Server 1 (= standby server) and Server 2 (= active server). Then the start script is run on Server 1 (= active server) and Server 2 (= standby server).

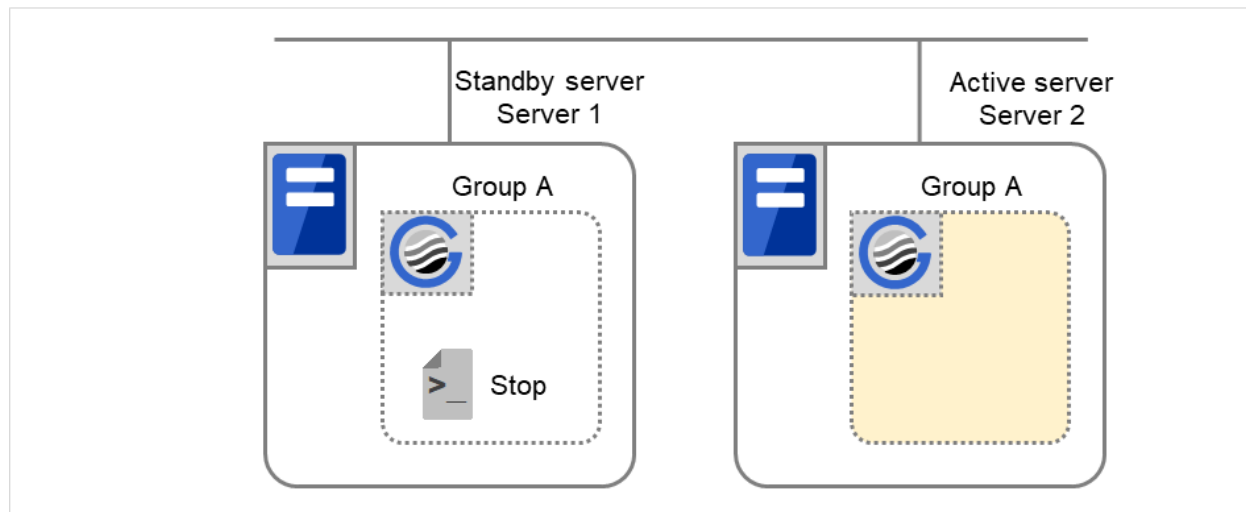

Fig. 3.66: Situation and script execution: moving Group A (1)

Fig. 3.67: Situation and script execution: moving Group A (2)

Fig. 3.68: Situation and script execution: moving Group A (3)

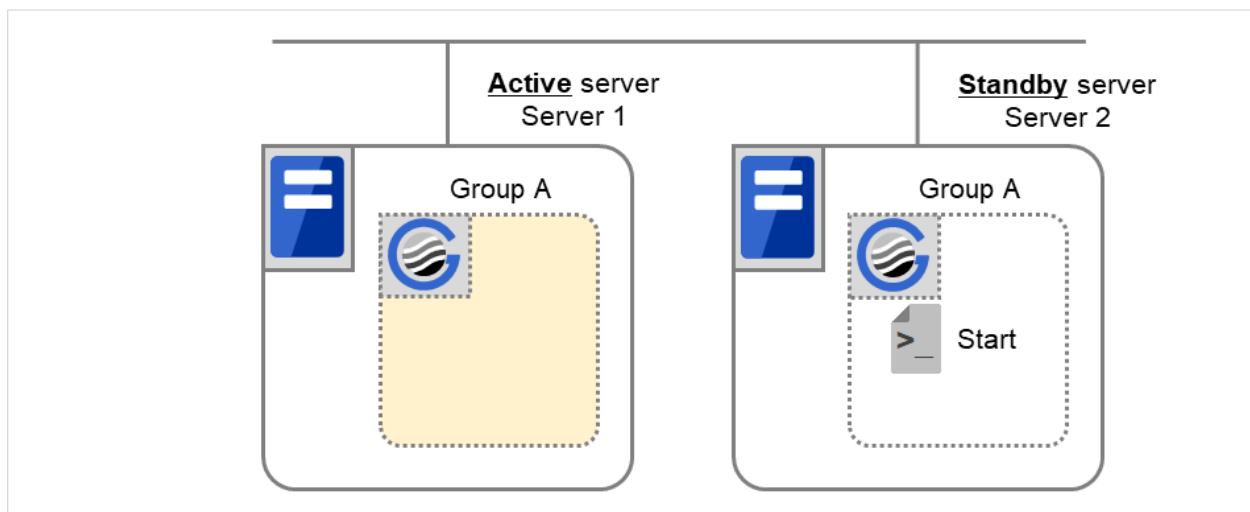

Fig. 3.69: Situation and script execution: moving Group A (4)

Environment variables for Stop

	Server 1	Server 2
CLP_EVENT	STANDBY	FAILOVER <sup>3</sup>
CLP_SERVER	HOME	OTHER

Environment variables for Start

<sup>3</sup>

The value of an environment variable for the stop script is changed to that for the last executed start script.  
In the transition case of "4. Moving of Group A", FAILOVER is applied without a cluster shutdown immediately preceding, or START is applied with a cluster shutdown done before the phase of "4. Moving of Group A".

	Server 1	Server 2
CLP_EVENT	START	STANDBY
CLP_SERVER	HOME	OTHER

### 3.6.6 Writing EXEC resource scripts

This section explains timing script execution described in the preceding topic relating to the actual script codes.

Numbers in brackets "*(number)*" in the following example script code represent the actions described in "*Execution timing of EXEC resource script*".

Group A start script: A sample of **start.sh**

```
#!/bin/sh
# *****
# *          start.sh          *
# *****

# Refer to the environment variable of the script execution factor to determine the
↳subsequent process.
if [ "$CLP_EVENT" = "START" ]
then
    # Refer to the environment variable of DISK connection information to determine
↳whether error handling is necessary.
    if [ "$CLP_DISK" = "SUCCESS" ]
    then
        # Here, write the normal startup process of the operation.
        # This process is to be performed at the timing of the following:
        #
        # (1) Normal startup
        # (5) Moving of Groups A and C
        #

        # Refer to the environment variable of the execution server to determine the
↳subsequent process.
        if [ "$CLP_SERVER" = "HOME" ]
        then
            # Here, write a process to be performed only for the normal startup of
↳the operation on the primary server.
            # This process is to be performed at the timing of the following:
            #
            # (1) Normal startup
            # (5) Moving of Groups A and C
            #

            else
                # Here, write a process to be performed only for the normal startup of
↳the operation on a non-primary server.
                #

                fi
            else
                # Here, write a disk-related error-handling process.
                #

                fi
        fi
    elif [ "$CLP_EVENT" = "FAILOVER" ]
    then
```

(continues on next page)

(continued from previous page)

```
# Refer to the environment variable of DISK connection information to determine_
↳whether error handling is necessary.
if [ "$CLP_DISK" = "SUCCESS" ]
then
    # Here, write the normal startup process of the operation.
    # This process is to be performed at the timing of the following:
    #
    # (3) Failover at Server 1 down
    #

    # Refer to the environment variable of the execution server to determine the_
    ↳subsequent process.
    if [ "$CLP_SERVER" = "HOME" ]
    then
        # Here, write a process to be performed only for the startup of the_
        ↳operation on the primary server after the failover.
        #

        else
            # Here, write a process to be performed only for the startup of the_
            ↳operation on a non-primary server after the failover.
            # This process is to be performed at the timing of the following:
            #
            # (3) Failover at Server 1 down
            #

            fi
        else
            # Here, write a disk-related error-handling process.
            #

            fi
    else
        # EXPRESSCLUSTER is not working.

    fi

# If the end code is zero (0), the EXEC resource activation is judged to be_
↳successful.
# Write to make a non-zero end code returned in response to an error in the script.
exit 0
```

Group A stop script: A sample of **stop.sh**

```
#!/bin/sh
# *****
# *          stop.sh          *
# *****

# Refer to the environment variable of the script execution factor to determine the
↳subsequent process.
if [ "$CLP_EVENT" = "START" ]
then
    if [ "$CLP_DISK" = "SUCCESS" ]
    then
        # Here, write the normal end process of the operation. This process is to be
↳performed at the timing of the following:
        #
        # (2) Normal shutdown
        #

        # Refer to the environment variable of the execution server to determine the
↳subsequent process.
        if [ "$CLP_SERVER" = "HOME" ]
        then
            # Here, write a process to be performed only for the normal end of the
↳operation on the primary server.
            # This process is to be performed at the timing of the following:
            #
            # (2) Normal shutdown
            #

            else
                # Here, write a process to be performed only for the normal end of the
↳operation on a non-primary server.
                #

            fi
        else
            # Here, write a disk-related error-handling process.
            #

        fi
    elif [ "$CLP_EVENT" = "FAILOVER" ]
    then

        # Refer to the environment variable of DISK connection information to determine
↳whether error handling is necessary.
        if [ "$CLP_DISK" = "SUCCESS" ]
        then
            # Here, write the normal end process to be performed after the failover.
            # This process is to be performed at the timing of the following:
            #
            # (4) Cluster shutdown after failover of Server 1
            # (5) Moving of Groups A and C
            #

            # Refer to the environment variable of the execution server to determine the
↳subsequent process.
            if [ "$CLP_SERVER" = "HOME" ]
```

(continues on next page)

(continued from previous page)

```

    then
        # Here, write a process to be performed only for the end of the operation
        ↪ on the primary server after the failover.
        #

    else
        # Here, write a process to be performed only for the end of the operation
        ↪ on a non-primary server after the failover.
        # This process is to be performed at the timing of the following:
        #
        # (4) Cluster shutdown after failover of Server 1
        # (5) Moving of Groups A and C

# If the end code is zero (0), the EXEC resource deactivation is judged to be
↪ successful.
# Write to make a non-zero end code returned in response to an error in the script.
exit 0

```

### 3.6.7 Tips for creating EXEC resource script

- If your script has a command that requires some time to complete, it is recommended to configure command completion messages to be always produced. This message can be used to determine the error when a problem occurs. There are two ways to produce the message:

- Specify the log output path of EXEC resource by writing the echo command in the script.

The message can be produced with the echo command. Specify the log output path in the resource properties that contain the script.

The message is not logged by default. For how to configure the settings for the log output path, see "Maintenance tab" in "*Details tab* - Tuning Properties". If the **Rotate Log** check box is not selected, pay attention to the available disk space of a file system because messages are sent to the file specified as the log output destination file regardless of the size of available disk space.

(Example: sample script)

```

echo "appstart.."
appstart
echo "OK"

```

- Write the clplogcmd command in the script.

The message can be produced to the Alert logs of the Cluster WebUI or syslog in OS with the clplogcmd command. For details on the clplogcmd command, see "*Outputting messages (clplogcmd command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

(Example: sample script)

```
clplogcmd -m "appstart.."
appstart
clplogcmd -m "OK"
```

### 3.6.8 Notes on EXEC Resource

- Script Log Rotate

When the Script Log Rotate function is enabled, a process is generated to mediate the log output. This intermediate process continues to work until the file descriptor is closed (i.e. until all the logs stop being output from the start and stop scripts and from a descendant process that takes over the standard output and/or the standard error output from the start and stop scripts). To exclude output from the descendant process from the log, redirect the standard output and/or the standard error output when the process is generated with the script.

- The start script and the stop script are executed by the root user.
- To start an application dependent on an environment variable, the script must set the environment variable as needed.

### 3.6.9 Details tab

Resource Properties | exec1 exec X

Info Dependency Recovery Operation **Details**

☐ User Application

☒ Script created with this product

Edit View Replace

Scripts

Type	Name
Start Script	start.sh
Stop Script	stop.sh

Tuning

OK Cancel Apply

#### User Application

Select this option to use executable files (executable shell scripts and binary files) on your server as scripts. Specify the local disk path on the server for each executable file name.

The executable files will not be distributed to each server. They should be placed on each server in advance. The cluster configuration data created by the Cluster WebUI does not contain these files. You cannot edit the script files using the Cluster WebUI.

#### Script created with this product

Select this option to use script files created by the Cluster WebUI as scripts. You can edit them using the Cluster WebUI as necessary. The cluster configuration data contains these script files.

### View

Click here to display the script file when you select **Script created with this product**.

### Edit

Click here to edit the script file when you select **Script created with this product**. Click Save to apply changes. You cannot rename the script file

With the **User Application** option selected, the **Enter application path** dialog box appears.

### Enter application path

Specify an exec resource executable file name.

The dialog box has a dark title bar with the text "Enter application path" in white. Below the title bar, the text "Enter the absolute path to the application." is displayed. There are two input fields: the first is labeled "Start\*" and the second is labeled "Stop". Both fields are empty. At the bottom right, there are two buttons: "OK" and "Cancel".

### Start (Within 1023 bytes)

Enter an executable file name to be run when the exec resource starts. The name should begin with "/." Arguments can also be specified.

### Stop (Within 1023 bytes)

Enter an executable file name to be run when the exec resource exits. The name should begin with "/." The stop script is optional.

For the executable file name, specify a full path name starting with "/" to a file on your cluster server.

Arguments can also be specified.

### Replace

Opens the **Open** dialog box with the **Script created with this product** option selected.

The contents of the script file selected in the **Resource Properties** are replaced with the one selected in the **Open** dialog box. If the selected script file is being viewed or edited, you cannot replace it. Select a script file, not a binary file such as an application program.

### Tuning

Opens the EXEC resource tuning properties dialog box. You can make advanced settings for the EXEC resource. If you want the PID monitor resource to monitor the exec resources, you have to set the start script to asynchronous.

### Exec Resource Tuning Properties

#### Parameter tab

The screenshot shows the 'Exec Resource Tuning Properties' dialog box with the 'Maintenance' tab selected. The dialog has two main sections: 'Start Script' and 'Stop Script'. Each section has radio buttons for 'Synchronous' (selected) and 'Asynchronous'. To the right of each 'Synchronous' option is a 'Timeout\*' field with a value of '1800' and the unit 'sec'. Below each 'Synchronous' section is an 'Execute on standby server' checkbox (unchecked) and a 'Timeout' field with a value of '10' and the unit 'sec'. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

Parameter	Maintenance
<b>Start Script</b>	
<input checked="" type="radio"/> Synchronous	Timeout* 1800 sec
<input type="radio"/> Asynchronous	
Execute on standby server	<input type="checkbox"/>
Timeout	10 sec
<b>Stop Script</b>	
<input checked="" type="radio"/> Synchronous	Timeout* 1800 sec
<input type="radio"/> Asynchronous	
Execute on standby server	<input type="checkbox"/>
Timeout	10 sec

OK Cancel Apply

### Common to all start scripts and stop scripts

#### Synchronous

Waits for the script to end when it is run. Select this option for executable files that are not resident (the process is returned immediately after the script completion).

#### Asynchronous

Does not wait for the script to end when it is run. Select this for resident executable files. The script can be monitored by PID monitor resource if **Asynchronous** is selected.

#### Timeout (1 to 9999)

When you want to wait for a script termination (when selecting **Synchronous**), specify how many seconds you want to wait before a timeout. This box is enabled when **Synchronous** is selected. Unless the script completes within the specified time, it is determined as an error.

#### Execute on standby server

Set whether the scripts are to be executed on the standby server. Enabling this parameter allows you to specify the timeout value (1 to 9999) for the execution.

#### Maintenance tab

The screenshot shows a dialog box titled "Exec Resource Tuning Properties". It has two tabs: "Parameter" and "Maintenance", with "Maintenance" currently selected. The "Log Output Path" field is empty. Below it is the "Rotate Log" checkbox, which is unchecked. Underneath that is the "Rotation Size" field, which contains the text "1000000", followed by the unit "byte". At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

**Log Output Path** (Within 1023 bytes)

Specify the redirect destination path of standard output and standard error output for EXEC resource scripts and executable files. If this box is left blank, messages are directed to /dev/null. The name should begin with "/."

If the **Rotate Log** check box is off, note the amount of available disk space in the file system because no limit is imposed on message output.

If the **Rotate Log** check box is on, the log file to be output is rotated. Note the following items.

You must specify a log output path within 1009 bytes. If you specify a path of 1010 bytes or more, the log is not output.

You must specify a log file name within 31 bytes. If you specify a log file name of 32 bytes or more, the log is not output.

When using multiple EXEC resources, the rotation size may not be normally recognized if you specify resources with the same file name, even if the paths differ (for example, /home/foo01/log/exec.log, /home/foo02/log/exec.log).

**Rotate Log**

Clicking **Rotate Log** when the **Rotate Log** check box is not checked outputs the execution logs of the EXEC resource script and the executable file without imposing any limit on the file size. Clicking **Rotate Log** when the **Rotate Log** check box is selected rotates and outputs messages.

**Rotation Size** (1 to 999999999)

If the **Rotate Log** check box is selected, specify a rotation size.

The structures of the log files to be rotated and output are as follows:

File name	Description
file_name for the <b>Log Output Path</b> specification	Newest log
file_name.pre for the <b>Log Output Path</b> specification	Previously rotated log

## 3.7 Understanding Disk resource

### 3.7.1 Dependencies of Disk resource

Disk resource is supported by the following versions of EXPRESSCLUSTER by default.

Group	Resource Type
Dynamic DNS resource	
Floating IP resource	
Virtual IP resource	
Volume manager resource	
AWS Elastic IP resource	
AWS Virtual IP resource	
AWS DNS resource	
Azure probe port resource	
Azure DNS resource	

### 3.7.2 Switching partitions

Switching partitions refer to partitions on shared disks connected to more than one server in a cluster.

Switching is done for each failover group according to the failover policy. By storing data required for applications on switching partitions, the data can be automatically used when failing over or moving failover group.

---

**Note:** For "raw" disk type, EXPRESSCLUSTER maps (binds) the switching partition to the raw device of the OS. If Execute Unbind is selected on the Disk Resource Tuning Properties, the unbind process is performed to deactivate the disk resource.

---

If switching partitions are not accessible with the same device name on all the servers, configure the server individual setup.

Fig. 3.70: Switching partitions (1)

Fig. 3.71: Switching partitions (2)

### 3.7.3 Device region expansion on disk resources

Follow the steps below to execute region expansion of the device. Be sure to execute the following steps on the server where the disk resource in question has been activated.

1. Deactivate a group to which the disk resource in question belongs by using a command such as `clpgrp`.
2. Confirm that no disks have been mounted by using a command such as `mount` and `df`.
3. Change the state of the disk from Read Only to Read Write by executing one of the following commands depending on the disk resource type.  
# `clproset -w -d <device-name>`
4. Execute region expansion of the device.
5. Change the state of the disk from Read Write to Read Only by executing one of the following commands depending on the disk resource type.  
# `clproset -o -d <device-name>`
6. Activate a group to which the disk resource in question belongs by using a command such as `clpgrp`.

### 3.7.4 Notes on disk resources

- EXPRESSCLUSTER controls accesses to the file system (mount/umount). Thus, do not configure the settings about mount/umount on the OS.  
(If the entry to is required `/etc/fstab`, please use the `noauto` option is not used ignore option.)
- The partition device name set to the disk resource is in the read-only mode on all servers in a cluster. Read-only status is released when the server is activated.
- If **Exclude Mount/Unmount Commands** is selected on the **Extension** tab of the **Cluster Prosperities**, it may take some time to activate or deactivate a disk resource because mount or unmount of disk resource, VxVM volume resource, NAS resource, and mirror resource is performed exclusively in the same server.
- When specifying path including symbolic link for mount point, Force Operation cannot be done even if it is chosen as operation in Detecting Failure.

Similarly, if a path containing "/" is specified, forced termination will also fail.

- If you want to prevent behalf of the device in OS startup, udev devices the Please set the device name.  
example: /dev/disk/by-label/<device-name>  
In starting the OS, if you want to prevent the device order from being switched, specify the udev device (e.g. /dev/disk/by-id/[device name]) for a device name.
- When a change is made at the run level on the OS, some device files of a partition device set as a disk resource might be created again. This may reset the read-only setting for the partition device set as a disk resource.

<When using a resource that has the disk type **LVM**>

- When using this setting, it is recommended to control a volume group by using a volume manager resource together. For details, see "[Understanding Volume manager resources](#)" of this guide.
- The volume is not defined on the EXPRESSCLUSTER side.
- Please do not select [zfs] for the File System.

<When using a resource that has the disk type **VXVM**>

- When using this setting, see "[Understanding Volume manager resources](#)".
- The volume is not defined on the EXPRESSCLUSTER side.
- No disk resource is needed when using only the accessible raw device (/dev/vx/rdisk/<disk-group-name>/<volume-name>) with the disk group imported and the volume started (raw access without setting up a file system on the volume).
- Please do not select [zfs] for the File System.

**Disk Type** Server Individual Setup

Select a disk type. You can only choose [disk].

Choose one of the types below.

- DISK

- RAW
- LVM
- VXVM

#### **File System** `Server Individual Setup`

You select a file system type created on the disk device. Choose one from the types described below. You may also directly enter the type. This setting is necessary when the setting to **Disk Type** is other than **raw**.

- ext3
- ext4
- xfs
- reiserfs
- vxfs
- zfs

#### **Device Name** (Within **1023 bytes**) `Server Individual Setup`

Select the disk device name to be used for disk resources. Otherwise, you can enter the device name. When other than [zfs] is selected for File System, the name should begin with "/". If File System is [zfs], specify the ZFS data set name.

#### **Raw Device Name** (within 1,023 bytes) `Server Individual Setup`

Enter the raw disk device name to be used for disk resources. This setting is necessary when the setting to **Disk Type** is **raw** or **vxvm**.

#### **Mount Point** (Within **1023 bytes**) `Server Individual Setup`

Enter the directory to mount the disk device. The name should begin with "/" This setting is necessary when the setting to **Disk Type** is other than **raw**.

#### **Tuning**

Opens the **Disk Resource Tuning Properties** dialog box. Make detailed settings on the dialog box.

#### **Disk Resource Tuning Properties**(when the setting to **Disk Type** is other than **raw**)

##### **Mount tab**

The detailed settings related to mount are displayed.

**Disk Resource Tuning Properties**

Mount Unmount Fsck

**Mount Option\***

**Timeout\***  sec

**Retry Count\***  time

### Mount Option

Enter options to give the mount command when mounting the file system on the disk device. More than one option is delimited with a comma ",".

A mount option sample

Setting item	Setting value
Device name	/dev/sdb5
Mount point	/mnt/sdb5
File system	ext3
Mount option	rw,data=journal

The mount command to be run with the above settings is:

```
mount -t ext3 -o rw,data=journal /dev/sdb5 /mnt/sdb5
```

### Timeout (1 to 999)

Enter how many seconds you want to wait for the mount command completion before its timeout when you mount the file system on the disk device.

If the file system has a large size of disk space, it may take some time for the command to complete. Make sure to specify the value that is enough for the mount command completion.

### Retry Count (0 to 999)

Enter how many times you want to retry to mount the file system on the disk device when one fails. If you set this to zero (0), mount will not be retried.

### Initialize

Clicking **Initialize** resets the values of all items to the default values.

### Unmount tab

The detailed settings related to unmount are displayed.

**Disk Resource Tuning Properties**

Mount Unmount **Fsync**

**Timeout\*** 120 sec

**Retry Count\*** 3 time

**Retry Interval\*** 5 sec

**Forced operation when failure is detected**

☒ kill

☐ No Operation

Initialize

OK Cancel Apply

**Timeout** (1 to 999)

Enter how many seconds you want to wait for the umount command completion before its timeout when you unmount the file system on the disk device.

**Retry Count** (0 to 999)

Enter how many times you want to retry to unmount the file system on the disk device when one fails. If this is set to zero (0), unmount will not be retried.

**Retry Interval** (0 to 999)

Enter the interval in which you want to retry unmounting the file system on the disk device when unmounting fails.

**Forced operation when failure is detected**

Select an action to be taken at an unmount retry if unmount is failed.

- kill  
Select this to try to kill the processes that are accessing the mount point. Not always the process can be killed.
- No Operation  
Select this not to try to kill the processes that are accessing the mount point.

**Initialize**

Clicking **Initialize** resets the values of all items to the default values.

**Fsync tab**

The detailed settings related to fsck are displayed. The tab appears only if [xfs] is set for the file system. If [zfs] is selected for the file system, it will be invalid.

Disk Resource Tuning Properties

fsck Action When Mount Failed

Execute

☒

Rebuilding of reiserfs

Execute

☐

Initialize

OK

Cancel

Apply

**fsck Option** (Within 1023 bytes)

Enter options to give to the fsck command when checking the file system on disk device. Options are delimited with a space. Specify options so that the fsck command does not work interactively.

Otherwise, you may not be allowed to mount until the "fsck timeout" elapses. When the file system is reiserfs, the fsck command works interactively. However, it can be avoided if EXPRESSCLUSTER gives "Yes" to reiserfsck.

**fsck Timeout** (1 to 9999)

Enter how many seconds you want to wait for the fsck command completion before its timeout when you check the file system on the disk device. If the file system has a large size of disk space, it may take some time for the command to complete. Make sure to specify the value that is enough for the mount command completion.

**fsck action before mount**

Select an fsck action before mounting file system on a disk device from the following choices:

- Always Execute  
fsck is executed before mounting the file system.

- Execute at Specified Count  
fsck is executed when resource is activated successfully within the count specified by **Count**.  
= Count (0 to 999)
- Not Execute  
fsck is not executed before mounting the file system.

---

**Note:** The number of times to execute fsck is not related to the check interval managed by a file system.

---

#### fsck Action When Mount Failed

Set an fsck action when detecting a mount failure on a disk device.

This setting is enabled when the setting of Mount **Retry Count** is other than zero.

- When the check box is selected:  
Mount is retried after running fsck.
- When the check box is not selected:  
Mount is retried without running fsck.

---

**Note:** It is not recommended to set "Not Execute" fsck action before performing mount. With this setting, disk resource does not execute fsck and disk resource cannot be failed over when there is an error that can be recovered by fsck in the switchable partition.

---

#### Rebuilding of reiserfs

Specify the action when reiserfsck fails with a recoverable error.

- When the checkbox is selected  
reiserfsck --fix-fixable is executed.
- When the checkbox is not selected  
Recovery is not performed even if reiserfsck fails with a recoverable error.

#### Initialize

Clicking **Initialize** resets the values of all items to the default values.

#### xfs\_repair tab

The detailed settings related to [xfs\_repair] are displayed. The tab appears only if [xfs] is set for the file system.

The screenshot shows a dialog box titled "Disk Resource Tuning Properties" with three tabs: "Mount", "Unmount", and "xfs\_repair". The "xfs\_repair" tab is selected. It contains the following fields and controls:

- xfs\_repair option**: A text input field.
- xfs\_repair Timeout\***: A text input field containing the value "7200", followed by the unit "sec".
- xfs\_repair Action When Mount Failed**: A section with a checkbox labeled "Execute". The checkbox is currently unchecked.
- Initialize**: A button located at the bottom left of the dialog.
- OK**, **Cancel**, and **Apply**: Buttons located at the bottom right of the dialog.

#### **xfs\_repair Option (Within 1023 bytes)**

Enter the option to give to the [xfs\_repair] command when checking the file system on the disk device. To enter multiple options, delimit each with a space.

#### **xfs\_repair Timeout (1 to 9999)**

Enter how many seconds you want to wait for the [xfs\_repair] command completion before its timeout when you check the file system on the disk device. If the file system has a large size of disk space, it may take some time for the command to complete. Make sure that the value to set is not too small.

#### **xfs\_repair Action When Mount Failed**

Set the [xfs\_repair] action when mounting the file system on the disk device fails. This setting is enabled when the setting of **Mount Retry Count** is other than zero.

- When the check box is selected:  
Mount is retried after running [xfs\_repair].
- When the check box is not selected:  
Mount is retried without running [xfs\_repair].

#### **Initialize**

Clicking **Initialize** resets the values of all items to the default values.

#### **Disk Resource Tuning Properties (when the setting to Disk Type is raw)**

##### **Unbind tab**

The detailed settings related to unbind are displayed.

**Disk Resource Tuning Properties**

Unbind

**Execute Unbind** ☐

**Timeout** 10 sec

**Retry Count** 3 time

Initialize

OK Cancel Apply

### Execute Unbind

Specify whether to execute unbind a raw disk device.

- When the check box is selected:  
Execute unbind a raw disk device.
- When the check box is not selected:  
Do not execute unbind a raw disk device.

### Timeout (1 to 999)

When the **Execute Unbind** check box is selected, Set the time-out for the unbind completion of the raw disk device.

### Retry Count (1 to 999)

When the **Execute Unbind** check box is selected, Specify the retry count to unbind the raw disk device when one fails.

### Initialize

Clicking **Initialize** resets the values of all items to the default values.

## 3.8 Understanding Floating IP resource

### 3.8.1 Dependencies of Floating IP resource

By default, this function does not depend on any group resource type.

### 3.8.2 Floating IP

Client applications can use floating IP addresses to access cluster servers. By using floating IP addresses, clients do not need to be aware of switching access destination server when a failover occurs or moving a group migration.

Floating IP addresses can be used on the same LAN and over the remote LAN.

Execute the [ifconfig] command or the API to assign an IP address to the OS. The floating IP resource automatically determines whether to execute the [ifconfig] command or the API.

When [ifconfig] command has a format other than the following, excute API.

```
eth0    Link encap:Ethernet HWaddr 00:50:56:B7:1B:C0
        inet  addr:192.168.1.113 Bcast:192.168.1.255 Mask:255.255.255.0
        inet6 addr: fe80::250:56ff:feb7:1bc0/64 Scope:Link
```

(The following **is** omitted.)

Clients access Server 1 at its floating IP (FIP) address .

Fig. 3.72: Access to the floating IP address (1)

Even if a failover occurs from Server 1 to Server 2, clients access the FIP address without being aware of the actual, changed destination.

Fig. 3.73: Access to the floating IP address (2)

**Address assignment**

An IP address to assign for floating IP address needs to meet the condition described below:

- Available host address which is in the same network address as the LAN that the cluster server belongs

Allocate as many IP addresses that meet the above condition as required (generally as many as failover groups). These IP addresses are the same as general host addresses, therefore, global IP addresses can be assigned such as Internet.

**Switching method**

For IPv4, MAC addresses on the ARP table are switched by sending ARP broadcasting packets from the server on which FIP resources are activated.

For IPv6, ARP broadcasting packets are not sent.

The table below shows the information of ARP broadcasting packets sent by EXPRESSCLUSTER:

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
FF	FF	FF	FF	FF	FF	MAC address						08	06	00	01
08	00	06	04	00	02	MAC address						Floating IP address			
MAC address						Floating IP address				00	00	00	00	00	00
00	00	00	00	00	00	00	00	00	00	00	00				

Fig. 3.74: ARP broadcasting packets sent by EXPRESSCLUSTER

**Routing**

You do not need to configure the settings for the routing table.

**Conditions to use**

Floating IP addresses are accessible to the following machines:

- Cluster server itself
- Other servers in the same cluster and the servers in other clusters
- Clients on the same LAN as the cluster server and clients on remote LANs

If the following conditions are satisfied, machines other than the above can also access floating IP addresses. However, connection is not guaranteed for all models or architectures of machines. Test the connection thoroughly by yourself before using those machines.

- TCP/IP is used for the communication protocol.
- ARP protocol is supported.

Even over LANs configured with switching hubs, floating IP address mechanism works properly. When a server goes down, the TCP/IP connection the server is accessing will be disconnected.

### 3.8.3 Notes on Floating IP resource

- Do not execute a network restart on a server on which floating IP resources are active. If the network is restarted, any IP addresses that have been added as floating IP resources are deleted.
- **IP address overlaps due to time-lag of the [ifconfig] command**

If the following is set to the floating IP resource, the failover of resources may fail:

- When a value smaller than the default is set to **Retry Count at Activation Failure**.
- When **Ping Retry Count** and **Ping Interval** are not set.

This problem occurs due to the following causes:

- Releasing IP address may take time depending on the specification of the **[ifconfig]** command after deactivating the floating IP address on the server from which the resource is failed over.
- On the activation of the floating IP address on the server to which the resource is failed over, if the ping command is run to the IP address to be activated in order to prevent dual activation, ping reaches the IP address because of the reason above, and the resource activation error occurs.

Make the following settings to avoid this problem:

- Set a greater value to **Retry Count at Activation Failure** of the resource (default: 5 times).
- Set greater values to **Ping Retry Count** and **Ping Interval**.

Clients access Server 1 at its floating IP (FIP) address.

Fig. 3.75: Configuration with a floating IP address (1): in a normal case

Server 1 crashes and a failover occurs.

However, while Server 1 cannot immediately release the FIP address, a ping reaches the address from Server 2. Then the FIP address is considered to have been duplicated, which leads to failure in activation on Server 2 (and failure in access from clients to the FIP address).

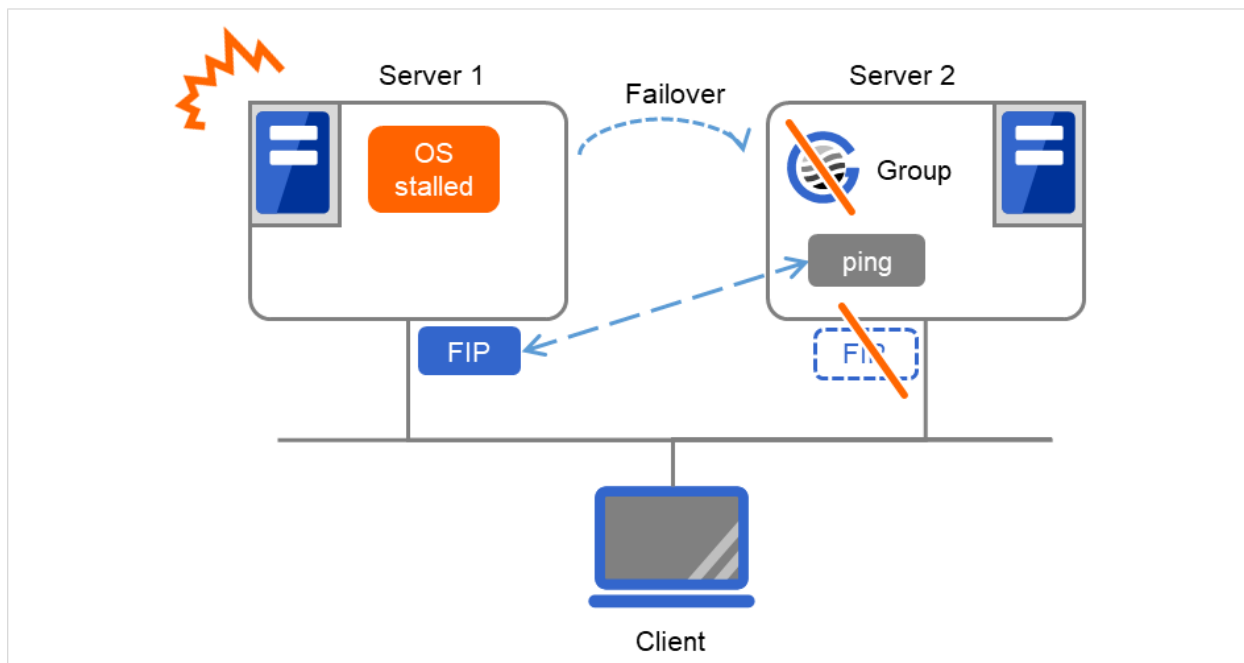

Fig. 3.76: Configuration with a floating IP address (2): when the failover fails

- IP address overlaps when OS is stalled

If OS stalls with the floating IP address activated, the resource failover may fail when the following settings are made:

- A value other than 0 is set to **Ping Timeout**.
- **Forced FIP Activation** is off.

This problem occurs due to the following causes:

- A part of OS stalls (as examples below) with the floating IP address activated.
  - \* Network modules are running and respond to ping from other nodes
  - \* A stall cannot be detected in the user-mode monitor resource
- When activating the floating IP address on the server to which the resource is failed over, if the ping command is executed to the IP address to be activated in order to prevent redundant activation, ping reaches the IP address because of the reason above, and the resource activation error occurs.

In the machine environment where this problem often occurs, this can be prevented by the settings below. However, both groups may be activated depending on the status of a stall, and server shutdown may occur depending on the timing of the activation of both groups. For details on activation of both groups, see "What causes servers to shut down" - "Recovery from network partition" in "The system maintenance information" in the "Maintenance Guide".

- Specify 0 to **Ping Timeout**  
Overlap check is not performed to the floating IP address.
- Specify "On" to **Forced FIP Activation**  
The floating IP address is activated forcibly even when the address is used on a different server.

- With **Ping Timeout** not set at zero (0) and **Forced FIP Activation** set at off

Due to the stalled OS on Server 1, a failover occurs with the FIP address activated. Immediately after that, however, there is a response to the ping command performed before the FIP address activation on Server 2. This activation fails for preventing dual activation.

Fig. 3.77: With **Ping Timeout** not set at zero (0) and **Forced FIP Activation** set at "Off"

- With **Ping Timeout** set at zero (0)

Due to the stalled OS on Server 1, a failover occurs with the FIP address activated. The FIP address activation succeeds on Server 2, where the ping command to the FIP address is not performed.

Fig. 3.78: With **Ping Timeout** set at zero (0)

- With **Ping Timeout** not set at zero (0) and **Forced FIP Activation** set at on

Due to the stalled OS on Server 1, a failover occurs with the FIP address activated. The FIP address activation forcibly succeeds on Server 2, regardless of the result of the ping command to the FIP address performed by Server 2.

Fig. 3.79: With **Ping Timeout** not set at zero (0) and **Forced FIP Activation** set at on

- MAC address of virtual NIC to which floating IP is allocated.  
When the floating IP resource fails over, the corresponding MAC address is changed because the MAC address of virtual NIC to which the floating IP is allocated is the MAC address of real NIC.
- Source address of IP communication from the running server when the resource activation.  
The source address from the server is basically the real IP of the server even though the floating IP resource has activated. When you want to change the source address to the floating IP, the settings are necessary on the application.
- When **Forced FIP Activation** is set to **ON**, if a floating IP address is activated, and then a machine in the same network segment connects to a floating IP address, the connection may be established with a machine that previously used that IP address.
- **floating IP resource does not supported by the environment that OpenVPN has started.**
- The NIC name (the name of a network interface card, such as eth0) is up to 15 characters long. If the length of the name exceeds 15 characters, the activation failure occurs. Modify the NIC name in such a case.
- Before activating a floating IP resource, [ping] is issued to check whether there is a duplicated IP address. Therefore, if rejection of ICMP reception via a firewall is set to a network device that uses a duplicated IP address, a floating IP address might be duplicated because the existence of duplicated IP addresses cannot be checked by using a [ping] command.

### 3.8.4 Waiting process for Floating IP resource deactivation

The following process takes place after deactivating of floating IP address.

#### 1. Waiting process

- Execute the [ifconfig] command or the API to acquire a list of IP addresses assigned to the OS. The floating IP resource automatically determines whether to execute the [ifconfig] command or the API. If no floating IP address exists in the IP address list, it is regarded as deactive.
- If a floating IP address exists in the IP addresses, one-second waiting takes place. This setting cannot be changed with the Cluster WebUI.
- The operation mentioned above is repeated for up to four times at maximum. This number of times cannot be changed by the Cluster WebUI.
- When it results in an error, whether the floating IP resource is regarded as having a deactivation error can be changed with **Status at Failure** under **Confirm I/F Deletion** on the **Deactivity Check** tab of the floating IP resource.

#### 2. Confirming process by the ping command

- The ping command is executed to check if there is a response from the floating IP address. If there is no response, it is regarded as deactive.
- When there is a response from the floating IP address, one-second waiting takes place. This setting cannot be changed with the Cluster WebUI.
- The operation mentioned above is repeated for up to four times at maximum. This number of times cannot be changed by the Cluster WebUI.
- The ping command is executed with one-second timeout. This timeout cannot be changed by the Cluster WebUI.
- When it results in an error, the status of floating IP resource can be changed in **Status at Failure** under **Confirm I/F Response** on the **Deactivity Check** on the **Deactivity Check** tab of the floating IP resource.

---

**Note:**

Acquisition of the list of IP addresses and floating address activation/deactivation using the [ifconfig] command timeout in 60 seconds (this is the default value).

This timeout value can be changed by the Clustew WebUI. For details, see the **Parameter tab** of the "*Details tab*".

---

### 3.8.5 Details tab

The screenshot shows a window titled "Resource Properties | fip1" with a close button. It has four tabs: "Info", "Dependency", "Recovery Operation", and "Details". The "Info" tab is active, displaying "Common server1 server2". Below this, there is a label "IP Address\*" followed by a text input field containing "10.0.0.12". A "Tuning" button is located below the input field. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

#### IP Address Server Individual Setup

Enter the floating IP address to be used. When setting the bonding, specify the bonding interface name by using "%" to separate. For details, see "*Bonding*" in "*7. Information on other settings*" in this guide.

- Example: 10.0.0.12%bond0

The floating IP resource searches for the address on a local computer having the same subnet mask, assuming there to be, by default, 24 mask bits for IPv4 or 128 bits for IPv6. Then, it assigns an alias to the relevant network interface to add a floating IP address.

To specify a number of mask bits explicitly, specify the address followed by **/number\_of\_mask\_bits**. (For an IPv6 address, be sure to specify **/number\_of\_mask\_bits**.)

Example: fe80::1/8

To specify a network interface explicitly, specify the address followed by **%interface\_name**.

Example: fe80::1/8%eth1

In the above example, a floating IP address with eight mask bits is added to network interface eth1.

When setting the tag VLAN Please specify the I / F name of tag VLAN, separated by the "%".

- example in the case of setting the tag VLAN: 10.0.0.12% eth0.1

In an environment in which an IPv6 address and the [ifconfig] command can be used, be sure to match the output format of the [ifconfig] command and the IP address notation of the floating IP because the environment is case sensitive.

#### Tuning

Opens the **Floating IP Resource Tuning Properties** dialog box where the detailed settings for the floating IP resource can be configured.

#### Floating IP Resource Tuning Properties

##### Parameter tab

Detailed settings on parameters for floating IP resource are displayed.

**Floating IP Resource Tuning Properties**

Parameter **Deactivity Check**

---

**ifconfig**

Timeout\*  sec

---

**Ping**

Interval\*  sec

Timeout\*  sec

Retry Count\*  time

Forced Fip Activation ☐

ARP Send Count\*  time

Judge NIC Link Down as Failure ☐

### ifconfig

The following is the detailed settings on getting IP addresses and on the [ifconfig] command executed for the activation and/or deactivation of the floating IP resource.

- **Timeout** (1 to 999)  
Make the setting of the timeout of [ifconfig] command. This parameter is not available in an environment in which the [ifconfig] command cannot be used. Therefore, specify 60 seconds (default value for such an environment).

### ping

These are the detailed settings of the ping command is used to check if there is any overlapped IP address before activating floating IP resource.

- **Interval** (0 to 999)  
Set the interval to issue the ping command.
- **Timeout** (0 to 999)  
Set timeout of the ping command.  
If zero is set, the ping command is not run.
- **Retry Count** (0 to 999)

Set retry count of the ping command.

- **Forced Fip Activation**

Specify whether to forcibly activate floating IP address when an overlapped IP address is detected by command check.

- When the check box is selected  
Forced activation is performed.
- When the check box is not selected  
Forced activation is not performed.

**ARP Send Count (0 to 999)**

Specify how many times you want to send ARP packets when activating floating IP resources.

If this is set to zero (0), ARP packets will not be sent.

**Judge NIC Link Down as Failure**

Specify whether to check for an NIC Link Down before the floating IP resource is activated. In some NIC boards and drivers, the required `ioctl()` may not be supported. To check the availability of the NIC Link Up/Down monitor, use the `[ethtool]` command provided by the distributor. For the check method using the `[ethtool]` command, see "*Note on NIC Link Up/Down monitor resources*" in "*Understanding NIC Link Up/Down monitor resources*" in this guide.

For bonding devices, it is judged as a failure when all the NIC composing the bonding are in the state of Link Down at activation.

- When the check box is selected  
In the case of an NIC Link Down, the floating IP resource is not activated.
- When the check box is not selected  
Even in the case of an NIC Link Down, the floating IP resource is activated.

**Initialize**

Clicking **Initialize** resets the values of all items to the default values.

**Deactivity Check tab**

Detailed settings on deactivity check of floating IP resource are displayed.

**Floating IP Resource Tuning Properties**

Parameter Deactivity Check

**Confirm I/F Deletion** ☒

**Status at Failure** ☐ Failure ☒ Not Failure

**Confirm I/F Response** ☒

**Status at Failure** ☐ Failure ☒ Not Failure

Initialize

OK Cancel Apply

#### Confirm I/F Deletion

- **Confirm I/F Deletion**  
Specify whether to confirm, whether the target floating IP address has been deleted successfully after the floating IP is deactivated.
- When the check box is selected  
Confirmation is performed.
- When the check box is not selected  
Confirmation is not performed.
- **Status at Failure**  
Specify how to handle a deactivation error of the floating IP resource.
- **Failure:**  
Treats as a deactivity failure of a floating IP resource.
- **Not Failure:**  
Do not treat as a deactivity failure of a floating IP resource.

#### Confirm I/F Response

- **Confirm I/F Response**  
Specify whether to confirm, using the ping command, whether the target floating IP address has been deleted successfully after the floating IP is deactivated.
- When the check box is selected  
Confirmation is performed.
- When the check box is not selected  
Confirmation is not performed.
- **Status at Failure**

Specify how to handle a deactivation error of the floating IP resource if the floating IP can be reached by the ping command.

- **Failure:**  
Treats as a deactivation failure of a floating IP resource.
- **Not Failure:**  
Do not treat as a deactivation failure of a floating IP resource.

## 3.9 Understanding Virtual IP resources

### 3.9.1 Dependencies of Virtual IP resources

By default, this function does not depend on any group resource type.

### 3.9.2 Virtual IP resources

Client applications can be connected to a cluster server by using a virtual IP address. The servers can be connected to each other by using a virtual IP address. By using a virtual IP address, switching from one server to the other to which a client is connecting remains transparent even if failover or moving of a failover group occurs. The graphic in the next page shows how virtual IP resources work in the cluster system.

Execute the `[ifconfig]` command or the API to assign an IP address to the OS. The floating IP resource automatically determines whether to execute the `[ifconfig]` command or the API. The following shows an example:

- For an environment such as RHEL 7 or later (including RHEL compatible operating systems) on which the `[ifconfig]` command cannot be used, the API is executed.
- For an environment such as RHEL 7 or later (including RHEL compatible operating systems) on which the `net-tools` package enables execution of the `[ifconfig]` command, the API is executed because the output format of the `[ifconfig]` command is not compatible with that of RHEL 6 or earlier.
- For an environment such as RHEL 6 on which the `[ifconfig]` command can be used, the `[ifconfig]` command is executed.

Fig. 3.80: Configuration with a virtual IP address (1)

Fig. 3.81: Configuration with a virtual IP address (2)

- Note on setting servers (1)  
Each cluster server on the same LAN requires being able to change the path by receiving RIP packets, or to resolve path information on the virtual IP address by accessing a router.
- Note on setting servers (2)  
Each cluster server in a separate segment requires being able to resolve path information on the virtual IP address by accessing a router.
- Note on setting virtual IP resources (1)  
Specify an IP address outside the LAN to which the cluster servers belong, and free from a collision with existing IP addresses.
- Note on setting routers (1)  
Each router requires being able to perform dynamic routing by interpreting RIP packets, or to resolve path information on the virtual IP address as static path information.
- Note on setting virtual IP resources (2)  
Be sure to specify a sender's IP address for each of the servers in order for RIP packets to be correctly sent.
- Note on setting routers (2)  
Set the flush timer of each router at a value within the heartbeat timeout value.
- Note on setting clients (1)  
Each client on the same LAN requires being able to change the path by receiving RIP packets, or to resolve path information on the virtual IP address by accessing a router.
- Note on setting clients (2)  
Each client in a separate segment requires being able to resolve path information on the virtual IP address by accessing a router.

### 3.9.3 Determining virtual IP address

An IP address used as a virtual IP address should satisfy the following conditions:

- The IP address should not be within the network address of the LAN to which the cluster belongs.
- The IP address should not conflict with existing network addresses.

Select one of the following allocation methods to meet the requirements above:

- Obtain a new network IP address for virtual IP address and allocate virtual IP address.
- Determine a network IP address from private IP address space and allocate virtual IP address. The following procedures are given as an example.
- Select one network address from 192.168.0 to 192.168.255 for virtual IP address.
- Allocate up to 64 host IP addresses for virtual IP address from the network address you have selected. (For example, select the network address 192.168.10 and allocate two host IP addresses: 192.168.10.1 and 192.168.10.254)
- Specify 255.255.255.0 to net mask of the virtual IP address.
- When you configure multiple virtual IP addresses, dummy virtual IP addresses may be required. For details, see "[Preparing for using Virtual IP resources](#)".
  - Private IP addresses are addresses for a closed network and they cannot be accessed using virtual IP address from outside of the network through internet providers.
  - Do not disclose path information of private IP addresses outside the organization.
  - Adjust the private IP addresses to avoid conflict with other address.

### 3.9.4 Preparing for using Virtual IP resources

If your cluster configuration satisfies the following conditions, you need to set a dummy virtual IP address which has same network address as a virtual IP address on each server.

- When multiple virtual IP resources exist in a cluster.
- Virtual IP resources whose network address and NIC alias name are same exist in a cluster.

---

**Note:** If a dummy virtual IP address cannot be configured, other virtual IP addresses assigned to the same NIC alias might be deleted by the OS when any virtual IP resource is deactivated.

---

A dummy virtual IP address should satisfy the following conditions:

- The IP address has a same network address as of a virtual IP resource, and is unique.
- The IP address can be prepared for each server constructing a cluster.
- The IP address is prepared for each NIC alias.

In the following settings, a dummy virtual IP address should be configured on each server.

- Virtual IP resource 1  
IP address 10.0.1.11/24  
NIC alias name eth1
- Virtual IP resource 2  
IP address 10.0.1.12/24

NIC alias name eth1

For example, set a dummy virtual IP address as follows:

- Dummy virtual IP address of Server 1  
IP address 10.0.1.100/24  
NIC alias name eth1:0
- Dummy virtual IP address of Server 2  
IP address 10.0.1.101/24  
NIC alias name eth1:0

Configure the OS by the following procedure so that dummy virtual IP addresses are enabled at OS startup.

In the following procedure, eth1 of server 1 is set to 10.0.1.100/24 as an example.

1. Perform one of the following procedures according to your distribution.

- For SUSE LINUX Enterprise Server:  
Edit the file on the following path. Add the italic parts on the setting information.

**Path**

*/etc/sysconfig/network/ifcfg-eth1-"MAC\_address\_of\_eth1"*

**Setting information**

```
BOOTPROTO='static'  
BROADCAST='10.0.0.255'  
IPADDR='10.0.0.1'  
MTU=''  
NETMASK='255.255.255.0'  
NETWORK='10.0.0.0'  
IPADDR_1='10.0.1.100'  
NETMASK_1='255.255.255.0'  
NETWORK_1='10.0.1.0'  
LABEL_1=1  
REMOTE_IPADDR=''  
STARTMODE='onboot'  
UNIQUE='xxxx'  
_nm_name='xxxx'
```

- For other than SUSE LINUX Enterprise Server:  
Create a file on the following path, and add the setting information.

**Path**

*/etc/sysconfig/network-scripts/ifcfg-eth1:0*

**Setting information**

```
DEVICE=eth1:0  
BOOTPROTO=static  
BROADCAST=10.0.1.255  
HWADDR=MAC_address_of_eth1  
IPADDR=10.0.1.100  
NETMASK_1=255.255.255.0  
NETWORK=10.0.1.0  
ONBOOT=yes  
TYPE=Ethernet
```

2. Restart the OS.

Dummy virtual IP addresses are enabled after the OS restart. Configure server 2 in the same manner.

Follow the procedure below when the settings above is required due to the cluster configuration change.

1. Stop a cluster. For the procedure, see "Suspending EXPRESSCLUSTER Stopping the EXPRESSCLUSTER daemon" in "Preparing to operate a cluster system" in the "Installation and Configuration Guide".
2. Disable the cluster daemon. For the procedure, see "Suspending EXPRESSCLUSTER Disabling the EXPRESSCLUSTER daemon" in "Preparing to operate a cluster system" in the "Installation and Configuration Guide".
3. Change the settings above.
4. Restart the OS, and check that the settings are applied.
5. Enable the cluster daemon. For the procedure, see "Suspending EXPRESSCLUSTER Enabling the disabled EXPRESSCLUSTER daemon" in "Preparing to operate a cluster system" in the "Installation and Configuration Guide".
6. Modify the cluster configuration. For the procedure, see "Modifying the cluster configuration data" in the "Installation and Configuration Guide".

### 3.9.5 Controlling path

To access to a virtual IP address from a remote LAN, path information of the virtual IP address must be effective to all routers on the path from the remote LAN to the LAN for cluster server. To be specific, the following condition must be satisfied:

- Routers on the cluster servers LAN interpret host RIP.
- Routers on the path from a cluster server to the remote server have the dynamic routing settings or information on the virtual IP address routes has configured as static routing settings.

### 3.9.6 Requirement to use virtual IP address

#### Environments where virtual IP address can be used

Virtual IP addresses can be accessed from the machines listed below. Virtual IP address mechanism functions properly even in a LAN where switching hubs are used. However, when a server goes down, TCP/IP that has been connected will be disconnected.

When using virtual IP addresses with a switching HUB that cannot be configured to create a host routing table by receiving host RIP, you need to reserve one new network address and configure virtual IP addresses so that the IP address of each server belongs to a different network address.

- **Cluster servers that belong to the same LAN which the server the virtual IP activates belongs to**

Virtual IP addresses can be used if the following conditions are satisfied:

- Machines that can change the path by receiving RIP packets.
- Machines that can resolve the path information of a virtual IP address by accessing a router.

- **Cluster servers that belongs to the different LAN from which the server the virtual IP activates belongs to**

Virtual IP addresses can be used if the following condition is satisfied:

- Machines that can resolve path information of the virtual IP address by accessing a router.

- **Clients that belongs to the same LAN which cluster servers belong to**

Virtual IP addresses can be used if the following conditions are satisfied:

- Machines that can change the path by receiving RIP packets.
- Machines that can resolve the path information of a virtual IP address by accessing a router.

- **Clients on remote LAN**

Virtual IP addresses can be used if the following condition is satisfied:

- Machines that can resolve path information of the virtual IP address by accessing a router.

### **3.9.7 Notes on Virtual IP resources**

- Do not execute a network restart on a server on which virtual IP resources are active. If the network is restarted, any IP addresses that have been added as virtual IP resources are deleted.

The following rule applies to virtual IP addresses.

- If virtual IP resources are not inactivated properly (e.g. when a server goes down), the path information of virtual IP resources is not deleted. If virtual IP resources are activated with their path information not deleted, the virtual IP addresses cannot be accessed until their path information is reset by a router or a routing daemon. Thus, you need to configure the settings of a flush timer of a router or a routing daemon. For a flush timer, specify the value within the heartbeat timeout value. For details on the heartbeat timeout, see "[Cluster properties](#)" in "[2. Parameter details](#)" in this guide.

- MAC address of virtual NIC to which virtual IP is allocated.

When the virtual IP resource fails over, the corresponding MAC address is changed because the MAC address of virtual NIC to which the virtual IP is allocated is the MAC address of real NIC.

- Source address of IP communication from the running server when the resource activation.

The source address from the server is basically the real IP of the server even though the virtual IP resource has activated. When you want to change the source address to the virtual IP, the settings are necessary on the application.

- Routing protocol used

If the routing protocol is set to "RIPver2," the subnet mask for transmitted RIP packets is "255.255.255.255" .

[Tuning](#)

[OK](#) [Cancel](#) [Apply](#)

#### IP Address Server Individual Setup

Enter the virtual IP address to use. To specify a number of mask bits explicitly, specify the address followed by /number\_of\_mask\_bits. (For an IPv6 address, be sure to specify /number\_of\_mask\_bits.)

#### NIC Alias Name Server Individual Setup

Enter the NIC interface name that activates the virtual IP address to be used.

#### Destination IP Address Server Individual Setup

Enter the destination IP address of RIP packets. IPv4 specifies the broadcast address and IPv6 specifies the router IPv6 address.

#### Source IP Address Server Individual Setup

Enter the IP address to bind when sending RIP packets. Specify the actual IP address activated on NIC which activates the virtual IP address.

To use an IPv6 address, specify a link local address as the source IP address.

**Note:** The source IP address should be set for individual servers, and set the actual IP address of each server. Virtual IP resources do not operate properly if a source address is invalid. In the **Common** tab, describes the source IP address of any server, other servers, please to perform the individual setting.

### Send Interval (1 to 30) Server Individual Setup

Specify the send interval of RIP packets.

### Use Routing Protocol Server Individual Setup

Specify the RIP version to use. For IPv4 environment, select RIPver1 or RIPver2. For IPv6 environment, select RIPngver1 or RIPngver2 or RIPngver3. You can select more than one routing protocols.

### Tuning

Opens **Virtual IP resource Tuning Properties**. You can make the advanced settings for the virtual IP resources.

### Virtual IP Resource Tuning Properties

#### Parameter tab

Detailed setting for virtual IP parameter is displayed.

The screenshot shows the 'Virtual IP Resource Tuning Properties' dialog box with the 'Parameter' tab selected. The dialog has a title bar and four tabs: 'Parameter', 'Deactivity Check', 'RIP', and 'RIPng'. The 'Parameter' tab is active, showing settings for 'ifconfig' and 'Ping'. The 'ifconfig' section has a 'Timeout\*' field set to '60' with a unit of 'sec'. The 'Ping' section has four fields: 'Interval\*' set to '1' (sec), 'Timeout\*' set to '1' (sec), 'Retry Count\*' set to '0' (time), and 'Forced Vip Activation' which is an unchecked checkbox. Below these is 'ARP Send Count\*' set to '1' (time), and 'Judge NIC Link Down as Failure' which is an unchecked checkbox. At the bottom left is an 'Initialize' button, and at the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

Section	Parameter	Value	Unit
ifconfig	Timeout*	60	sec
Ping	Interval*	1	sec
	Timeout*	1	sec
	Retry Count*	0	time
	Forced Vip Activation	<input type="checkbox"/>	
	ARP Send Count*	1	time
Judge NIC Link Down as Failure		<input type="checkbox"/>	

Initialize

OK Cancel Apply

#### ifconfig

The following is the detailed settings on getting IP addresses and on the ifconfig command executed for the activation and/or deactivation of the virtual IP resource.

- **Timeout** (1 to 999)

Make the setting of the timeout of [ifconfig] command. This parameter is not available in an environment in which the [ifconfig] command cannot be used. Therefore, specify 60 seconds (default value for such an environment).

### Ping

In this box, make detailed settings of the ping command used to check for any overlapped IP address before activating the virtual IP resource.

- **Interval** (0 to 999)  
Specify the interval to issue the ping command in seconds.
- **Timeout** (0 to 999)  
Specify the time-out for the ping command in seconds.  
When 0 is specified, the ping command is not run.
- **Retry Count** (0 to 999 )  
Specify how many retries of issuing the ping command are attempted.
- **Forced Vip Activation**  
Use this button to configure whether to forcibly activate the virtual IP address when an overlapped IP address is found using the ping command.
- When the check box is selected  
Forcefully activate the virtual IP address.
- When the check box is not selected  
Do not forcefully activate the virtual IP address.

### ARP Send Count (0 to 999)

Specify how many times you want to send ARP packets when activating virtual IP resources.

If this is set to zero (0), ARP packets will not be sent.

### Judge NIC Link Down as Failure

Specify whether to check for an NIC Link Down before the virtual IP resource is activated. In some NIC boards and drivers, the required ioctl( ) may not be supported. To check the availability of the NIC Link Up/Down monitor, use the [ethtool] command provided by the distributor. For the check method using the [ethtool] command, see "*Note on NIC Link Up/Down monitor resources*" in "*Understanding NIC Link Up/Down monitor resources*" in this guide.

- When the check box is selected  
In the case of an NIC Link Down, the floating IP resource is not activated.
- When the check box is not selected  
Even in the case of an NIC Link Down, the floating IP resource is activated. This operation is the same as before.

### Initialize

Click **Initialize** to reset the values of all items to their default values.

### Deactivity Check tab

Detailed settings on deactivity check of virtual IP resource are displayed.

**Virtual IP Resource Tuning Properties**

Parameter Deactivity Check RIP RIPng

Confirm I/F Deletion ☒

Status at Failure ☐ Failure ☒ Not Failure

Confirm I/F Response ☒

Status at Failure ☐ Failure ☒ Not Failure

Initialize

OK Cancel Apply

#### Confirm I/F Deletion

After deactivating the virtual IP, the cluster makes sure that the given virtual IP address disappeared successfully. Configure if failure is treated as the IP resource deactivity failure.

- Failure:  
Treats as a deactivity failure of a virtual IP resource.
- Not Failure:  
Does not treat as a deactivity failure of a virtual IP resource.

#### Confirm I/F Response

After deactivating a virtual IP, a cluster makes sure that the given virtual IP address cannot be accessed by the ping command. Configure reaching the virtual IP address by the ping command is treated as deactivity failure.

- Failure:  
Treats as a deactivity failure of a virtual IP resource.
- Not Failure:  
Do not treat as a deactivity failure of a virtual IP resource.

#### RIP tab

Detailed settings on RIP of virtual IP resource are displayed.

#### Next Hop IP Address

Enter the next hop address (address of the next router). Next hop IP address can be omitted. It can be specified for RIPver2 only. You cannot specify a netmask or prefix.

#### Metric (1 to 15)

Enter a metric value of RIP. A metric is a hop count to reach the destination address.

#### Port

On **Port Number**, a list of communication ports used for sending RIP is displayed.

#### Add

Add a port number used for sending RIP. Clicking this button displays the dialog box to enter a port number.

#### Port No.

Enter a port number to be used for sending RIP, and click **OK**.

#### Edit

A dialog box to enter a port number is displayed. The port selected in the **Port Number** is displayed. Edit it and click **OK**.

### Remove

Click **Remove** to remove the selected port on the **Port Number**.

### RIPng tab

Detailed settings on RIPng of virtual IP resource are displayed.

The screenshot shows the 'Virtual IP Resource Tuning Properties' dialog box with the 'RIPng' tab selected. The 'Metric\*' field contains the value '1'. Below it, the 'Port' section has 'Edit', 'Add', and 'Remove' buttons. The 'Port Number' section displays '521'. At the bottom left is an 'Initialize' button, and at the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

### Metric (1 to 15)

Enter a metric value of RIPng. A metric is a hop count to reach the destination address.

### Port

On **Port Number**, a list of ports used for sending RIPng is displayed.

### Add

Add a port number used for sending RIPng. Clicking this button displays the dialog box to enter a port number.

The screenshot shows the 'Port Number Settings' dialog box. It features a 'Port Number\*' field with a text input box. At the bottom right are 'OK' and 'Cancel' buttons.

### Port No.

Enter a port number to be used for sending RIPng, and click **OK**.

### **Edit**

A dialog box to enter a port number is displayed. The port selected in the **Port Number** is displayed. Edit it and click **OK**.

### **Remove**

Click **Remove** to remove the selected port on the **Port Number**.

## 3.10 Understanding Mirror disk resources

### 3.10.1 Dependencies of Mirror disk resource

By default, this function depends on the following group resource type.

Group resource type
Floating IP resource
Virtual IP resource
AWS Elastic IP resource
AWS Virtual IP resource
AWS DNS resource
Azure probe port resource
Azure DNS resource

### 3.10.2 Mirror disk

#### Mirror disk

Mirror disks are a pair of disks that mirror disk data between two servers in a cluster.

The following figure illustrates mirroring disk data by a pair of Mirror disk 1 with Server 1 and Mirror disk 2 with Server 2:

Fig. 3.82: Mirror disk configuration (1)

Fig. 3.83: Mirror disk configuration (2)

**Data partition**

Partitions where data to be mirrored (such as application data) is stored are referred to as data partitions. Allocate data partitions as follows:

- Data partition size  
The size of data partition should be 1GB or larger but smaller than 1TB.  
(Less than 1TB size is recommended from the viewpoint of the construction time and the restoration time of data.)
- Partition ID  
83(Linux)
- If Execute initial mkfs is selected in the cluster configuration information, a file system is automatically created when a cluster is generated.
- EXPRESSCLUSTER is responsible for the access control (mount/umount) of file system. Do not configure the settings that allow the OS to mount or unmount a data partition.

**Cluster partition**

Dedicated partitions used in EXPRESSCLUSTER for mirror partition controlling are referred to as cluster partition.

Allocate cluster partitions as follows:

- Cluster partition size  
1024MB or more. Depending on the geometry, the size may be larger than 1024MB, but that is not a problem.
- Partition ID  
83(Linux)
- A cluster partition and data partition for data mirroring should be allocated in a pair.
- Do not make the file system on cluster partitions.
- EXPRESSCLUSTER performs the access control of the file system (mount/umount) as a device to mount the mirror partition device. Thus, do not configure the settings to mount or unmount the cluster partition on the OS side.

### **Mirror Partition Device (/dev/NMPx)**

One mirror disk resource provides the file system of the OS with one mirror partition. If a mirror disk resource is registered to the failover group, it can be accessed from only one server (it is generally the primary server of the resource group).

Typically, the mirror partition device (dev/NMPx) remains invisible to users (AP) because they perform I/O via a file system. The device name is assigned so that the name does not overlap with others when the information is created by the Cluster WebUI.

- EXPRESSCLUSTER is responsible for the access control (mount/umount) of file system. Do not configure the settings that allow the OS to mount or unmount a data partition.  
Mirror partition's (mirror disk resource's) accessibility to applications is the same as switching partition (disk resources) that uses shared disks.
- Mirror partition switching is done for each failover group according to the failover policy.

### **Mirror disk connect**

Maximum of two mirror disk connects can be registered per mirror disk resource.

- When two mirror disk connects are registered, operations such as switching etc. are as follows:
  - The paths used to synchronize mirror data can be duplicated. By setting this, mirror data can be synchronized even when one of the mirror disk connects becomes unavailable due to such as disconnection.
  - The speed of mirroring does not change.
  - When mirror disk connects switch during data writing, mirror break may occur temporarily. After switching mirror disk connects completes, differential mirror recovery may be performed.
  - When mirror disk connects switch during mirror recovery, mirror recovery may suspended. If the setting is configured so that the automatic mirror recovery is performed, mirror recovery automatically resumes after switching mirror disk connects completes. If the setting is configured so that the automatic mirror recovery is not performed, you need to perform mirror recovery again after switching mirror disk connects completes.

For the mirror disk connect settings, see "*Cluster properties*" "*Interconnect tab*" in "*2. Parameter details*" in this guide.

- Disk partition

It is possible to allocate a mirror disk partition (cluster partition, data partition) on a disk, such as root partition or partition, where the OS is located

- When maintainability at a failure is important:  
It is recommended to allocate a disk for mirror which is not used by the OS (such as root partition, swap partition).
- If LUN cannot be added due to H/W RAID specifications:  
If you are using hardware/RAID preinstall model where the LUN configuration cannot be changed, you can allocate a mirror partition (cluster partition, data partition) in the disk where the OS (root partition, swap partition) is located.

Example: Adding a SCSI disk to each server to create a pair of mirroring disks.

Fig. 3.84: Adding a disk for a mirror partition

Example: Using available area of the IDE disks of each server on which OS of is stored to create a pair of mirroring disks.

The following figure illustrates using the free space of each disk as a mirror partition device (cluster partition and data partition):

Fig. 3.85: Using the free space of each disk for a mirror partition

- Disk allocation

You may use more than one disk for mirror disk. You may also allocate multiple mirror partition devices to a single disk.

Example: Adding two SCSI disks to each server to create two pairs of mirroring disks.

The following figure illustrates using mirror partitions prepared from two pairs of disks on which partitions of the same size are created:

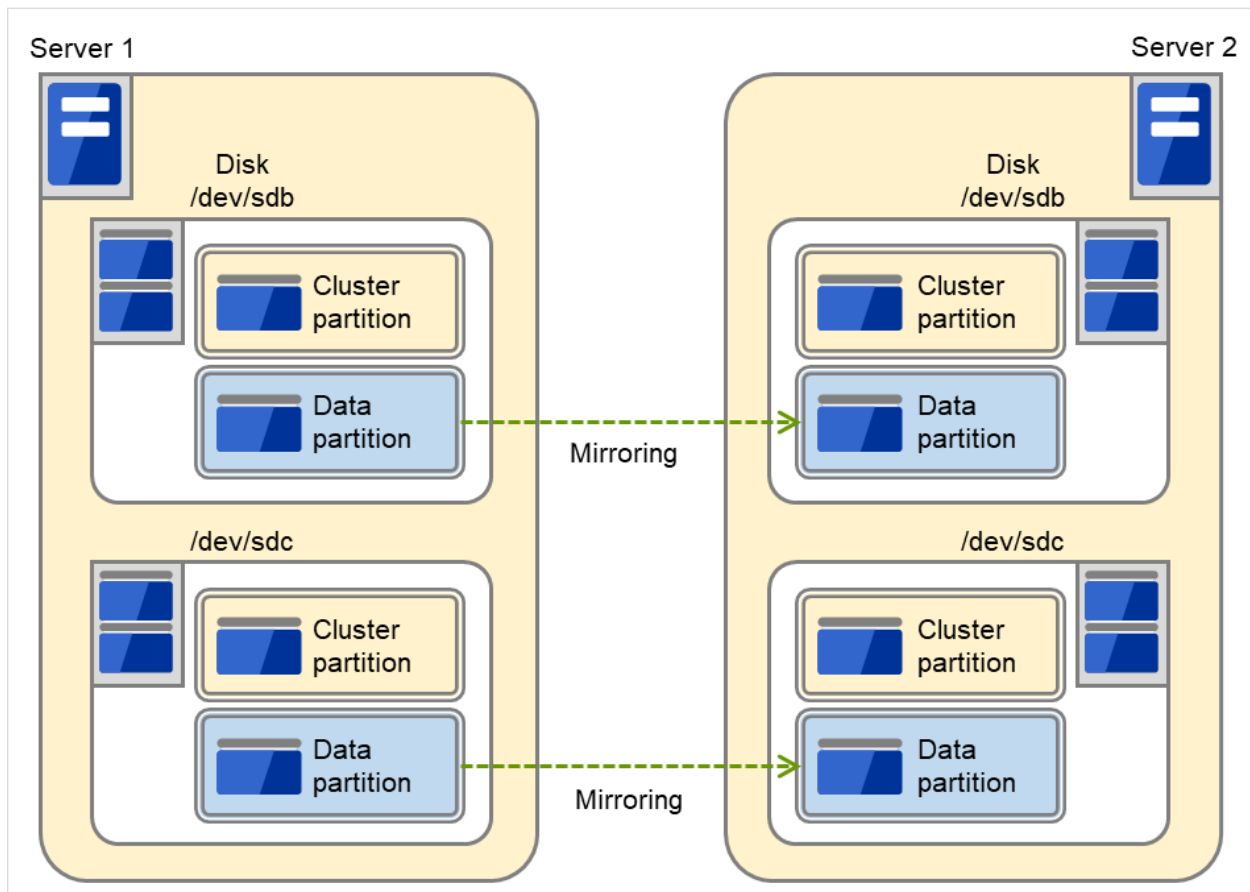

Fig. 3.86: Using two pairs of disks as mirror partitions

Example: Adding a SCSI disk for each server to create two mirroring partitions.

The following figure illustrates each disk on which two pairs of a cluster partition and a data partition are created:

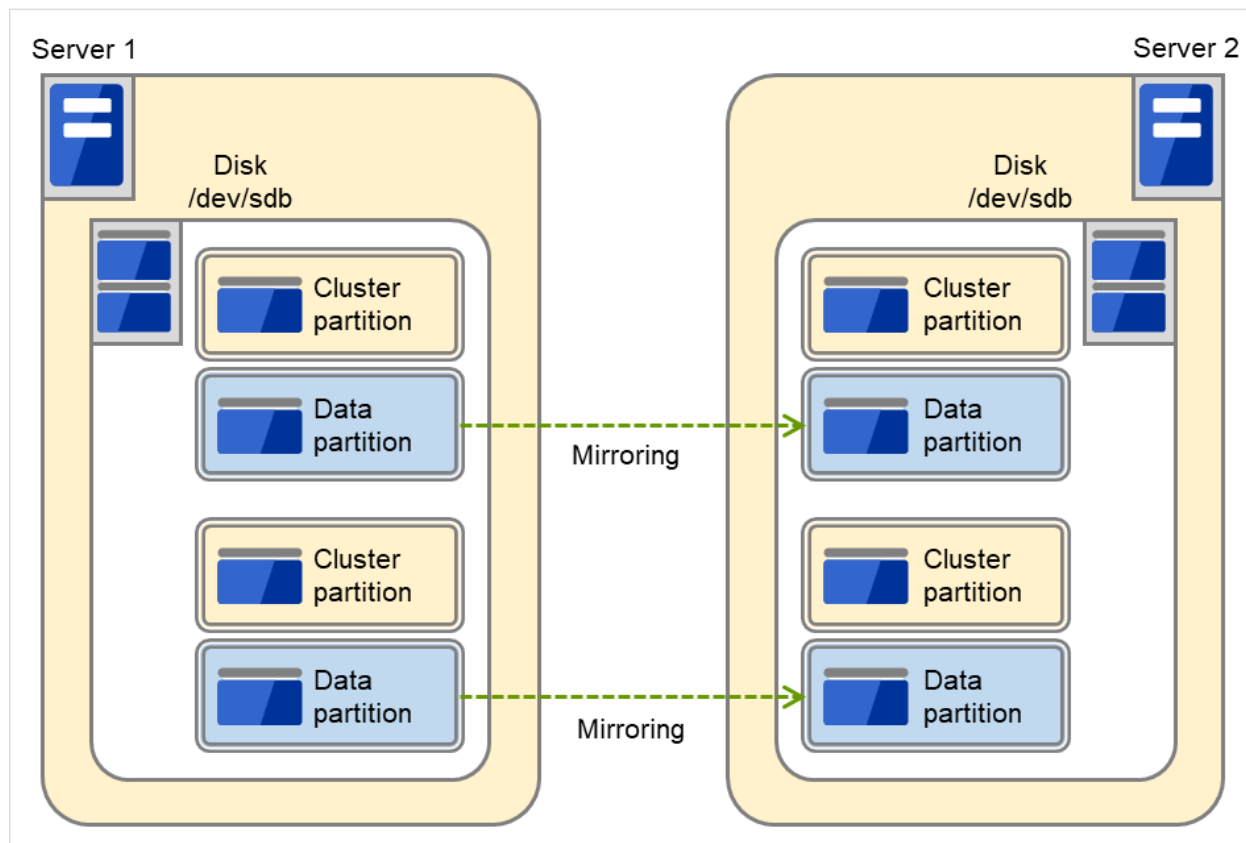

Fig. 3.87: Using multiple areas of each disk for two mirror partitions

### 3.10.3 Understanding mirror parameters

#### Mirror Data Port Number

Set the TCP port number used for sending and receiving mirror data between servers. It needs to be configured for individual mirror disk resources.

The default value is displayed when a mirror disk resource is added in Cluster WebUI based on the following condition:

- A port number of 29051 or later which is unused and the smallest

#### Heartbeat Port Number

Set the port number that a mirror driver uses to communicate control data between servers. It needs to be configured for individual mirror disk resources.

The default value is displayed when a mirror disk resource is added in Cluster WebUI based on the following condition:

- A port number of 29031 or later which is unused and the smallest

#### ACK2 Port Number

Set the port number that a mirror driver uses to communicate control data between servers. It needs to be configured for individual mirror disk resources.

The default value is displayed when a mirror disk resource is added in Cluster WebUI based on the following condition:

- A port number of 29071 or later which is unused and the smallest

### The maximum number of request queues

Configure the number of queues for I/O requests (write requests) from the higher layer of the OS to the mirror disk driver. If a larger value is selected, the write performance will improve but more physical memory will be required.

Note the following when setting the number of queues:

- The improvement in the performance is expected when a larger value is set under the following conditions:
  - Large amount of physical memory is installed on the server and there is plenty of available memory.

### Connection Timeout

This timeout is used for the time passed waiting for a successful connection between servers when recovering mirror or synchronizing data.

### Send timeout

This timeout is used:

- For the time passed waiting for the write data to be completely sent from the active server to the standby server from the beginning of the transmission at mirror return or data synchronization.

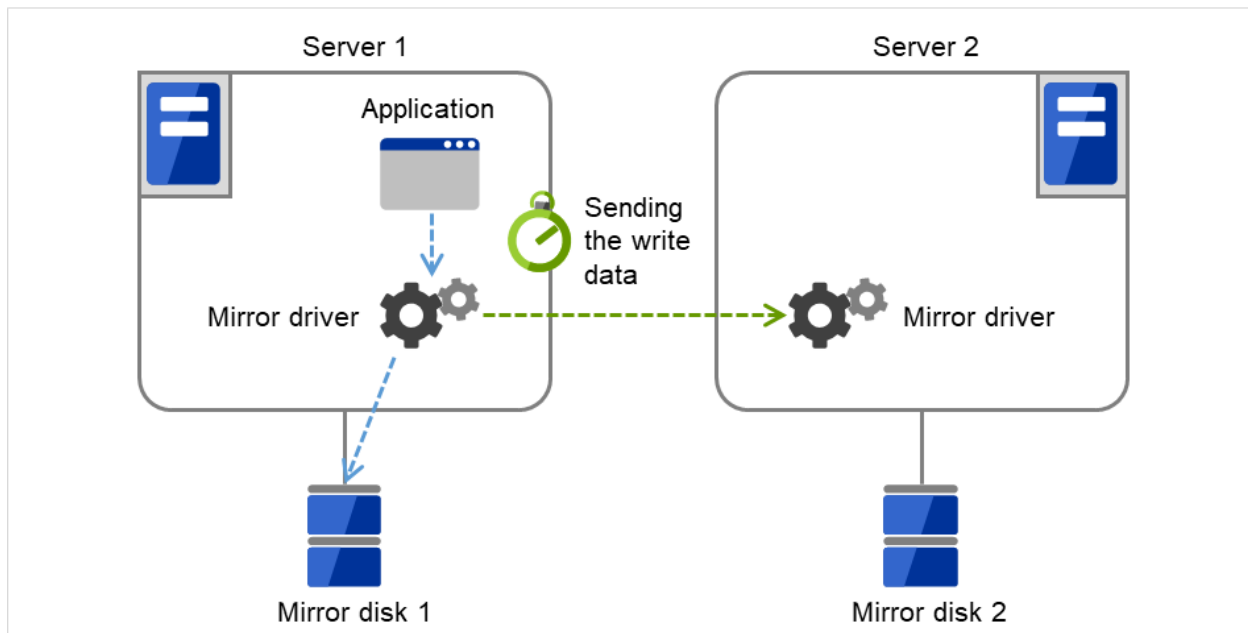

Fig. 3.88: Send timeout (for the write data)

In detail, this timeout is to wait for write data to be completely stored in the send buffer of a network (TCP) once data storing begins. If the TCP buffer is full and there is no free space, a timeout occurs.

- For the time interval for checking if the ACK send (in which the active server notifies the standby server of write completion) is necessary.

Fig. 3.89: Send timeout (for checking for the ACK send)

#### Receiving timeout

- This timeout is used for the time passed waiting for the standby server to completely receive the write data from the active server from the beginning of the transmission.

Fig. 3.90: Receiving timeout

#### Ack timeout

- This timeout is used for the time passed waiting for the active server to receive the ACK notifying the

completion of write once the active server begins sending write data to the standby server.

If the ACK is not received within the specified timeout time, the difference information is accumulated to the bitmap for difference on the active server.

Fig. 3.91: ACK timeout (for the ACK to be received from the standby server)

If you use the synchronous mode, a response to an application might wait until receiving the ACK or until it's timeout.

If you use the asynchronous mode, a response to an application is returned after writing to the active server's disk. (This response does not wait for ACK).

- This timeout is used for the time passed waiting for the standby server to receive the ACK from the active server after the standby server completely sent the ACK notifying the completion of write.

If the ACK for the active server is not received within the specified timeout time, the difference information is accumulated to the bitmap for difference on the standby server.

Fig. 3.92: ACK timeout (for the ACK to be received from the active server)

- This timeout is used for the time passed waiting for the copy source server to receive the ACK notifying completion from the copy destination server after it began the data transmission when recovering mirror.

Fig. 3.93: ACK timeout (for the ACK to be received for recovery data)

When the sending amount of the recovery data reaches the Recovery Data Size, 1 ACK is returned (Recovery Data Size is described below.)

Therefore when the Recovery Data Size becomes larger, sending becomes more efficient. But if an ACK

timeout occurred, re-send data size also becomes larger.

### Heartbeat Interval (1 to 600)

Heartbeat interval (sec) for checking the soundness of the mirror disk connect between the mirror drivers of two servers. Use the default whenever possible.

### ICMP Echo Reply Receive Timeout (1 to 100)

Value used for heartbeat that is performed to check the soundness of the mirror disk connect between the mirror drivers of two servers. The maximum wait time from when ICMP Echo Request is sent until ICMP Echo Reply is received from the destination server. If ICMP Echo Reply is not received even if this timeout elapses, the reception is repeated for up to the ICMP Echo Request retry count, explained later. Use the default whenever possible.

Fig. 3.94: ICMP echo reply receive timeout

### ICMP Echo Request Retry Count (1 to 50)

Enter how many times you want to retry at the maximum to send ICMP Echo Request if ICMP Echo Reply from the destination server to ICMP Echo Request cannot be received before the ICMP Echo Reply receive timeout. Use the default whenever possible.

Adjustment between the ICMP Echo Reply receive timeout and ICMP Echo Request retry count.

You can adjust the sensitivity that determines mirror disk connect disconnection by adjusting the ICMP Echo Reply receive timeout and ICMP Echo Request retry count.

- **Increasing the value**
  - Case in which a network delay occurs in a remote location
  - Case in which a temporary failure occurs in a network
- **Decreasing the value**
  - Case in which the time for detecting a network failure is to be reduced

### **Difference Bitmap Update Interval**

Information to be written to the bit map for difference is temporarily accumulated in memory, and is written to the cluster partition at regular intervals. This interval is used for the standby server to check whether this is information to write to the bit map as well as to perform a write.

### **Difference Bitmap Size**

Users can set the difference bitmap size.

If the data partition size is large, there are times efficiency of differential copy can be better by enlarging the size of difference bitmap.

However, memory efficiency could be deteriorated. Please use the default value under normal conditions.

This setting is needed to be set before establishing a mirror disk resource and/or a hybrid disk resource in the cluster. If the mirror disk resource and/or the hybrid disk resource already exist in the cluster, the setting cannot be changed.

### **Initial Mirror Construction**

Specify if configure initial mirroring<sup>4</sup> when activating cluster for the first time after the cluster is created.

- Execute the initial mirror construction  
An initial mirroring is configured when activating cluster for the first time after the cluster is created.  
The time that takes to construct the initial mirror is different from ext2/ext3/ext4/xfs and other file systems.
- Do not execute initial mirror construction  
Does not configure initial mirroring after constructing a cluster.  
Before constructing a cluster, it is necessary to make the content of mirror disks identical without using EXPRESSCLUSTER.

### **Initial mkfs**

Specify if initial file creation in the data partition of the mirror disk is configured when activating cluster for the first time after the cluster is created.

- Execute initial mkfs  
The first file system is created when activating cluster for the first time immediately after the cluster is created.
- Do not execute initial mkfs  
Does not create a first file system to the data partition in the mirror disk when activating cluster for the first time immediately after the cluster is created.  
You can configure the settings so that the initial mkfs setting is not executed when a file system has been set up in the data partition of the mirror disk and contains data to be duplicated, which does not require file system construction or initialization by mkfs.  
The mirror disk partition<sup>5</sup> configuration should fulfill mirror disk resource requirements.

If **Does not execute initial mirror construction** is selected, **Execute initial mkfs** cannot be chosen. (Should mkfs be performed for the active and standby data partitions, even immediately after mkfs is performed, differences will arise between the active data partition and standby data partition for which mkfs has been executed. Therefore, when initially executing mkfs, initial mirror construction (copying of the active data partition and the standby data partition) is also required. If [Execute initial mirror construction] is selected, [Execute initial mkfs] can be chosen.)

### **Number of Queues**

In the **Asynchronous** mode, specify the maximum number of queues in which write requests to the remote disk are held. For details on asynchronous mode setting, see "[Details tab](#)".

---

<sup>4</sup> Regardless of the existence of the FastSync Option, the entire data partition is copied.

<sup>5</sup> There must be a cluster partition in a mirror disk. If you cannot allocate a cluster partition when the single server disk is the mirroring target, take a backup and allocate the partition.

In cases such as when a slow network is used or if the amount of data requiring transmission (synchronization) increases as the amount written to the mirror increases, those data waiting for transmission (waiting for synchronization to be complete) are accumulated in these queues. Then, if the network speed becomes fast or if the amount of data transmitted (synchronized) decreases along with reduced writes to the mirror, data in queues waiting for transmission are transmitted. In this way, queues are used to absorb the increase and decrease in written data and the network speed change and to transmit data to the network.

If a larger value is set for the number of queues to absorb the increase and decrease in synchronous data, usually, the maximum time until synchronization is complete (Ack timeout) should also be set to a larger value.

These queues are created in the memory space. However, if the number of data units waiting for synchronization to be completed exceeds the maximum number of queues, then the excess is recorded and stored as a file.

By setting a larger maximum number of queues, the I/O performance may be improved, but more memory space will be used. For information on the required memory size, see "Installation requirements for EXPRESSCLUSTER" - "Software" - "Required memory and disk size" in the "Getting Started Guide".

In the case that the maximum number of queues is too large, if a synchronization timeout (Ack timeout) or a mirror communication break occurs while writing a large amount of data, an enormous volume of queue processes will arise at a time, possibly leading to extremely high load.

### Rate limitation of Mirror Connect

In the **Asynchronous** mode, the server tries to transfer data that has been temporarily queued to the standby server as quickly as possible. For this reason, if the channel for mirror disk connect is used for other applications, the communication band may become busy, hindering other communications.

In this case, by imposing bounds on the communication band for mirror connect communication, the impact on other communications can be reduced.

If, however, the communication band for mirror disk connect is smaller than the average amount of data to be written to the mirror disk, the queued data cannot be fully transferred to the standby server, and at last the maximum number of queues is reached, causing mirroring to interrupt (mirror break). The bandwidth should be large enough to allow data to be written into the business application.

---

**Note:** This function imposes a limit on the communication band by having a maximum one-second pause when the total amount of data to be transferred per second exceeds the configured value. If the amount of data to be written to the disk at one time exceeds the configured value, the expected level of performance may not be achieved. For example, when the amount of data to be transferred to a copy of a mirror disk at one time is 64 KB, even if you set a communication band limit of 64 KB or less per second, the actual amount of communication during copy can be greater than the configured value.

---

### History File Store Directory

Specify the directory of a file in which, if the maximum number of queues created in the memory is exceeded in the **Asynchronous** mode, the excess is recorded.

It is recommended to prepare a disk for storing the history file and set the **History File Store Directory** on the disk, because the amount of I/O to/from the mirror disk may increase the I/O load on the **History File Store Directory**.

### Size Limitation of History File

Specify the maximum accumulation in the history file in the **Asynchronous** mode. When the accumulation reaches the maximum, a mirror break occurs.

### Compress Data

Specify whether to compress mirror synchronous data (in the case of **Asynchronous** mode) or mirror recovery data before transmission. If a slow network is used, compressing transmission data can reduce the amount of data to be transmitted.

---

#### Note:

- Compression may increase the CPU load at data transmission.
  - In a slow network, compression reduces the amount of data transmitted, so a reduction in time can be expected compared to uncompressed data. Conversely, in a fast network, increases in compression processing time as well as load are more noticeable than a reduction in transfer time, so a reduction in time might not be expected.
  - If most of data has a high compression efficiency, compression reduces the amount of data transmitted, so a reduction in time can be expected compared to uncompressed data. Conversely, if most of data has a low compression efficiency, not only the amount of data transmitted is not reduced, but also the compression processing time and load increase, in which case a reduction in time might not be expected.
- 

### Mirror agent send time-out

Time-out for the mirror agent waiting to complete processing data after sending a request to the other server.

Fig. 3.95: Mirror agent send time-out

### Mirror agent receiving time-out

Time-out for the mirror agent waiting to start receiving data after the mirror agent creates a communication socket with the other server.

Fig. 3.96: Mirror agent receiving time-out

**Recovery Data Size (64 to 32768)**

Specify the size of data in mirror recovery between two servers in one processing. The default size is used in general.

- Specify a larger size
  - It takes less time to completely process mirror recovery because the number of data exchanges between two servers decreases.
  - During mirror recovery, disk performance may degrade.  
(This is because, if the disk read range for mirror recovery data and the disk write range for a file system overlap, access is excluded and a wait occurs until the first processing is complete.  
In a slow network environment, if there is a large amount of recovery data, a single data transfer for mirror recovery will take more time. If a normal disk access for mirror data and this data transfer range for mirror recovery overlap, disk access is awaited until the transfer is complete. This may lead to degraded disk performance.  
Therefore, specify a smaller size, especially for a slow network environment.)
- Specify a smaller size
  - Sending/receiving data between two servers gets segmented and the possibility for a timeout to occur is decreased with a slow network speed or a high server load.
  - Because the number of exchanges between two servers increases, mirror recovery takes more time, especially in a network where delay occurs easily.

**Encrypt mirror communication**

Choose whether to encrypt data passing through mirror disk connects.

The applied encryption algorithm is Advanced Encryption Standard (GCM), which supports up to 256-bit key length. The encryption is recommended if the channels of mirror disk connects include external lines.

### 3.10.4 Examples of mirror disk construction

If you are using a disk that has been used as a mirror disk in the past, you must format the disk because old data exists in its cluster partition. For the initialization of a cluster partition, refer to the "Installation and Configuration Guide".

- Execute the initial mirror construction

Executing initial mkfs

First, install EXPRESSCLUSTER. Next, execute the initial mkfs to the disk connected to Server 1 and that to Server 2.

Fig. 3.97: Example of mirror disk construction: executing both initial mkfs and initial mirror construction (1)

Then start the initial mirror construction. Completely copy the content of Mirror disk 1 on Server 1 to Mirror disk 2 on Server 2.

Fig. 3.98: Example of mirror disk construction: executing both initial mkfs and initial mirror construction (2)

- Execute the initial mirror construction  
Not executing initial mkfs

First, create application data to be duplicated (if available before the cluster construction) in the data partition (e.g. initial database) of Mirror disk 1 on the active server in advance. For information on the partition configuration, refer to "3.10.2. *Mirror disk*". Next, install EXPRESSCLUSTER on each of Server 1 and Server 2.

Fig. 3.99: Example of mirror disk construction: executing only initial mirror construction (1)

Then start the initial mirror construction. Completely copy the content of Mirror disk 1 on Server 1 to Mirror disk 2 on Server 2.

Fig. 3.100: Example of mirror disk construction: executing only initial mirror construction (2)

- Do not execute initial mirror construction  
Not executing initial mkfs

The following is an example of making the mirror disks of both servers identical. (This cannot be done after constructing the cluster. Be sure to perform this before the cluster construction.)

#### **Example 1**

Copying partition images of a disk

First, create application data to be duplicated (if available before the cluster construction) in the data partitions (e.g. initial databases) of Mirror disk 1 on the active server in advance. For information on the partition configuration, refer to "3.10.2. *Mirror disk*".

Fig. 3.101: Example of mirror disk construction: copying partition images (1)

Remove Mirror disk 2 from the standby server (Server 2), and connect the disk to the active server (Server 1).

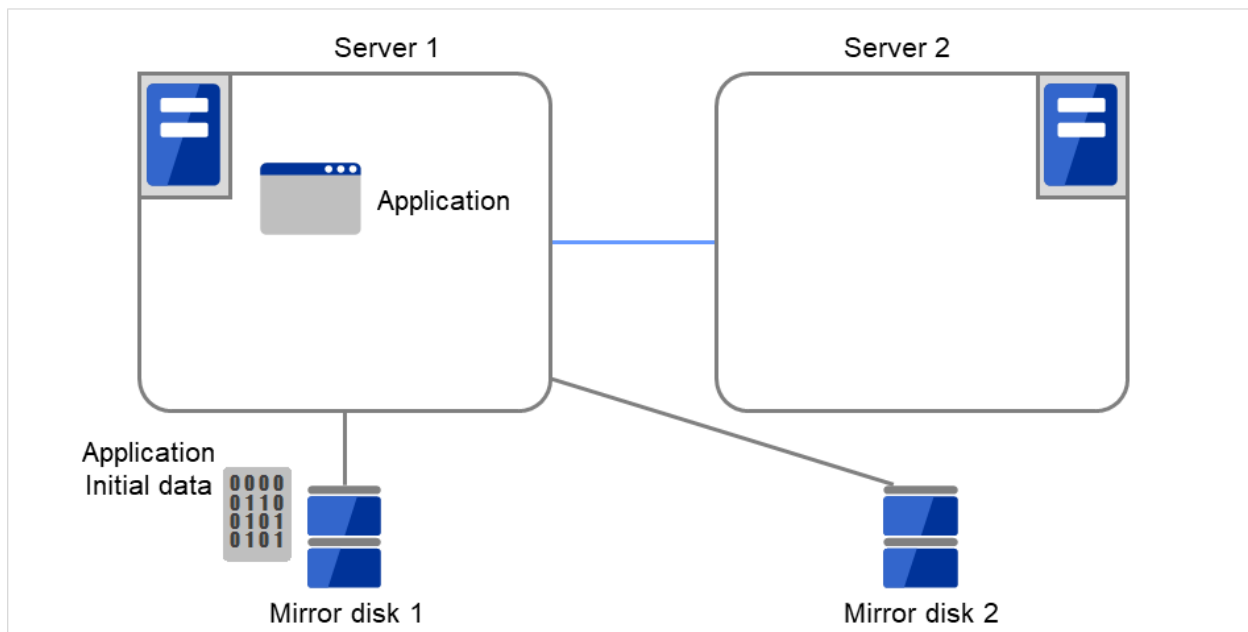

Fig. 3.102: Example of mirror disk construction: copying partition images (2)

With Mirror disk 1 (for the active server) unmounted, copy the full content of the data partitions on Mirror disk 1 to those on Mirror disk 2 (e.g. by using the dd command).  
Note that copying via the file system brings different partition images.

Fig. 3.103: Example of mirror disk construction: copying partition images (3)

Remove Mirror disk 2 from the active server (Server 1), and return the disk to the standby server (Server 2).

Then install EXPRESSCLUSTER.

After that, construct the cluster as described in "Do not execute initial mirror construction. Not executing initial mkfs" .

The initial construction/synchronization of the mirror partition is not to be performed.

Fig. 3.104: Example of mirror disk construction: copying partition images (4)

## Example 2

Copying by a backup device

First, create application data to be duplicated (if available before the cluster construction) in the data partitions (e.g. initial databases) of Mirror disk 1 on the active server in advance.

For information on the partition configuration, refer to "3.10.2. *Mirror disk*".

Fig. 3.105: Example of mirror disk construction: using a backup device (1)

Connect a backup device to the active server (Server 1).

Back up data in the data partitions on Mirror disk 1, by using a command (e.g. dd command) for partition image backup.

Fig. 3.106: Example of mirror disk construction: using a backup device (2)

Connect the backup device to the standby server (Server 2). Then, to a backup device on Server 2,

move the medium used for backing up the data on the active server (Server 1).

Fig. 3.107: Example of mirror disk construction: using a backup device (3)

Install EXPRESSCLUSTER.

After that, construct the cluster as described in "Do not execute initial mirror construction. Not executing initial mkfs". The initial construction/synchronization of the mirror partition is not to be performed.

Fig. 3.108: Example of mirror disk construction: using a backup device (4)

### 3.10.5 Notes on mirror disk resources

- If both servers cannot access the identical partitions under the identical device name, configure the server individual setting.
- If **Exclude Mount/Unmount Commands** is selected on the **Extension** tab in **Cluster Properties**, activation/deactivation of mirror resource may take time because mount/umount is performed exclusively to disk resource, VxVM volume resource, NAS resource, and mirror resource in the same server.
- When specifying path including symbolic link for mount point, Force Operation cannot be done even if it is chosen as operation in Detecting Failure.  
Similarly, if a path containing "/" is specified, forced termination will also fail.
- Disks using stripe set, volume set, mirroring, stripe set with parity by Linux md cannot be specified for the cluster partition and data partition.
- Volumes by Linux LVM can be specified for the cluster partition and data partition.  
For SuSE Linux, volumes by LVM or MultiPath cannot be used for the cluster partition or data partition.
- Mirror disk resources (mirror partition devices) cannot be the targets of stripe set, volume set, mirroring, stripe set with parity by Linux md or LVM.
- When the geometries of the disks used as mirror disks differ between the servers:

The size of a partition allocated by the fdisk command is aligned by the number of blocks (units) per cylinder.

Allocate data partitions to achieve the following data partition size and direction of the initial mirror construction.

**Source server <= Destination server**

"Source server" refers to the server with the higher failover policy in the failover group to which a mirror resource belongs.

"Destination server" refers to the server with the lower failover policy in the failover group to which a mirror resource belongs.

If the data partition sizes differ significantly between the copy source and the copy destination, initial mirror construction may fail. Be careful, therefore, to secure data partitions of similar sizes.

Make sure that the data partition sizes do not cross over 32GiB, 64GiB, 96GiB, and so on (multiples of 32GiB) on the source server and the destination server. For sizes that cross over multiples of 32GiB, initial mirror construction may fail.

Examples)

Combination	Data partition size		Description
	On server 1	On server 2	
OK	30GiB	31GiB	OK because both are in the range of 0 to 32GiB.
OK	50GiB	60GiB	OK because both are in the range of 32GiB to 64GiB.
NG	30GiB	39GiB	Error because they are crossing over 32GiB.
NG	60GiB	70GiB	Error because they are crossing over 64GiB.

- Do not use the `O_DIRECT` flag of the `open()` system call for a file used in a mirror disk resource. Examples include the Oracle parameter `filesystemio_options = setall`.
- Do not specify a mirror partition device (such as `/dev/NMP1`) as the monitor target in the `READ (O_DIRECT)` disk monitoring mode.
- For the data partition and the cluster partition of mirror disk resources, use disk devices with the same logical sector size on all servers. If you use devices with different logical sector sizes, they do not operate normally. They can operate even if they have different sizes for the data partition and the cluster partition.

Examples)

Combination	Logical sector size of the partition				Description
	Server 1	Server 1	Server 2	Server 2	
	Data partition	Cluster partition	Data partition	Cluster partition	
OK	512B	512B	512B	512B	The logical sector sizes are uniform.
OK	4KB	512B	4KB	512B	The data partitions have a uniform size of 4 KB, and the cluster partitions have a uniform size of 512 bytes.
NG	4KB	512B	512B	512B	The logical sector sizes for the data partitions are not uniform.
NG	4KB	4KB	4KB	512B	The logical sector sizes for the cluster partitions are not uniform.

- Do not use HDDs and SSDs in combination for the disks used for the data partition and the cluster partition of mirror disk resources. If you used them in combination, optimum performance cannot be obtained. Even if disks with different disk types are used for the data partition and the cluster partition, they can operate.

Examples)

Combination	Logical sector size of the partition				Description
	Server 1	Server 1	Server 2	Server 2	
	Data partition	Cluster partition	Data partition	Cluster partition	
OK	HDD	HDD	HDD	HDD	The disk types are uniform.
OK	SSD	HDD	SSD	HDD	The data partitions are of the uniform disk type of SSD, and the cluster partitions are of the uniform type of HDD.
NG	SSD	HDD	HDD	HDD	As the data partitions, both HDD and SSD are used.
NG	SSD	SSD	SSD	HDD	As the cluster partitions, both HDD and SSD are used.

### 3.10.6 mount processing flow

The mount processing needed to activate the mirror disk resource is performed as follows:

With **none** specified for the file system, the mount processing does not occur.

1. Is the device already mounted?

When already mounted -> To X

2. Is fsck set to be run before mounting?

Timing at which to run fsck -> Run fsck for the device.

3. Mount the device.

Mounted successfully -> To O

4. Is mounting set to be retried?

When retry is not set -> To X

5. When fsck(xfs\_repair) is set to be run if mounting fails:

When fsck has run successfully in 2. -> Go to **6.**

When mounting fails due to a timeout in 3. -> Go to **6.**

Other than the above -> Run fsck(xfs\_repair) for the device.

6. Retry mounting of the device.

Mounted successfully -> To O

7. Has the retry count for mounting been exceeded?

Within the retry count -> Go to **6.**

The retry count has been exceeded -> To X

**O** The resource is activated (mounted successfully).

**X** The resource activation has failed (not mounted).

### 3.10.7 umount processing flow

The umount processing to deactivate the mirror disk resource is performed as follows:

With **none** specified for the file system, the umount processing does not occur.

1. Is the device already unmounted?

When already unmounted -> To X

2. Unmount the device.

Unmounted successfully -> To O

3. Is unmount set to be retried?

When retry is not set -> To X

4. Is the device still mounted? (Is the mount point removed from the mount list and is the mirror device in the unused status?)

No longer mounted -> To O

5. Try KILL for the process using the mount point.

6. Retry unmount of the device.

Unmounted successfully -> To O

7. Is the result other than the unmount timeout and is the mount point removed from the mount list?

The mount point has already been removed.

-> Wait until the mirror device is no longer used.

(Wait no more than a length of time equal to the unmount timeout.)

8. Has the retry count for unmount been exceeded?

Within the retry count -> Go to **4.**

The retry count is exceeded -> To X

**O** The resource is stopped (unmounted successfully).

**X** The resource stop has failed (still mounted, or already unmounted).

### 3.10.8 Conditions under which the mirror status becomes abnormal

The following lists the most common situations in which the status of a mirror disk resource changes from normal (GREEN) to abnormal (RED).

- Due to the disconnection of communication (mirror disconnect), stoppage of the standby server, etc., mirror synchronization between the active and standby servers fails, leading to differences between the servers.  
The standby server does not retain the latest data, so enters the abnormal (RED) state.
- Settings are made so that mirror data is not synchronized, causing differences between the active and standby servers.  
The standby server does not retain the latest data, so enters the abnormal (RED) state.
- A mirror disk disconnection (mirroring interruption) operation is performed.  
The standby server enters the abnormal (RED) state.
- Mirror recovery is interrupted during mirror recovery (during mirror re-synchronization).  
The standby server has not completed copying, so enters the abnormal (RED) state.
- The active server does not execute cluster shutdown normally due to server down, etc.  
(The activated mirror disk resource stops without switching to the deactivated state.)  
The mirror disk of the server enters the abnormal (RED) state after the server starts.
- After a mirror disk is activated by starting only one server, the server is stopped without performing mirror synchronization, and then the other server is started and the mirror disk is activated.  
Because the mirror disks of the two servers are updated individually, those disks enter the abnormal (RED) state.  
If the mirror disks of the two servers are updated individually as described above, it is not possible to automatically judge the mirror disk of which server should act as the copy source, so automatic mirror recovery is not performed. In this case it is necessary to execute forced mirror recovery.
- Due to the disconnection of communication (mirror disconnect), reboot of the standby server, etc., mirror synchronization between the active and standby servers fails, causing differences between the servers and, later, the active server fails to execute cluster shutdown normally due to a server down, etc.  
In this case, if the server normally fails over to the standby server later, both servers enter the abnormal (RED) state after the servers start.  
In this case, automatic mirror recovery is not performed, either. Rather, it is necessary to execute forced mirror recovery.

For details on how to refer to the status of a mirror, see the following:

- Online manual
- 8. *EXPRESSCLUSTER command reference*
  - *Displaying the mirror status (clpmdstat command)*
    - \* *Display examples*
      - Displaying the status of mirror disk resource

For details on how to perform the mirror recovery or forcible mirror recovery, see the following:

- 9. *Troubleshooting*
  - *Troubleshooting*
    - \* *Recovering from mirror breaks*
    - \* *Automatically recovering from mirroring*

### 3.10.9 Details tab

Resource Properties | md1 md ×

Info Dependency Recovery Operation **Details**

Common server1 server2

**Mirror Partition Device Name\***

**Mount Point\***

**Data Partition Device Name\***

**Cluster Partition Device Name\***

**File System\***

**Mirror Disk Connect**

#### Mirror Partition Device Name

Select a mirror partition device name to be associated with the mirror partition.

Device names of mirror disk resource/hybrid disk resource that have already been configured are not displayed on the list.

#### Mount Point (Within 1023 bytes) Server Individual Setup

Specify a directory to mount the mirror partition device. The name should begin with "/."

#### Data Partition Device Name (Within 1023 bytes) Server Individual Setup

Specify a data partition device name to be used for a disk resource.

The name should begin with "/."

#### Cluster Partition Device Name (Within 1023 bytes) Server Individual Setup

Specify a cluster partition device name to be paired with the data partition.

The name should begin with "/."

#### File System

You select a file system type to be used on the mirror partition. Choose one from the list box. You may also directly enter the type.

- ext2
- ext3
- ext4
- xfs
- jfs
- reiserfs
- none (no file system)

### Mirror Disk Connect

Add, delete or modify mirror disk connects. In the **Mirror Disk Connects** list, I/F numbers of the mirror disk connects used for mirror disk resources are displayed.

Selection of Mirror Disk Connect

Mirror Disk Connect

Mirror Disk Connects

Order	MDC
1	mdc1

Available Mirror Disk Connect

MDC

No Available Mirror Disk Connect

OK Cancel Apply

In **Available Mirror Disk Connect**, mirror disk connect I/F numbers that are currently not used are displayed.

- Set mirror disk connects on the Cluster Properties.
- Maximum of two mirror disk connects can be used per mirror disk resource. For the behavior when two mirror disk connects are used, see "[Mirror disk](#)".
- For details on how to configure mirror disk connects, see the "Installation and Configuration Guide".

### Add

Use **Add** to add a mirror disk connect. Select the I/F number you want to add from **Available Mirror Disk Connect** and then click **Add**. The selected number is added to the **Mirror Disk Connects** list.

### Remove

Use **Remove** to remove mirror disk connects to be used. Select the I/F number you want to remove from the **Mirror Disk Connect list** and then click **Remove**. The selected number is added to **Available Mirror Disk Connect**.

### Order

Use the arrows to change the priority of mirror disk connects to be used. Select the I/F number you want to change from the **Mirror Disk Connect list** and then click the arrows.

### Tuning

Opens the **Mirror Disk Resource Tuning Properties** dialog box. You make detailed settings for the mirror disk resource there.

### Mirror disk resource tuning properties

#### Mount tab

The advanced settings of mount are displayed.

This does not appear with **none** selected from **File System** under the **Details** tab of the **Resource Properties** dialog box.

The screenshot shows the 'Mirror Disk Resource Tuning Properties' dialog box with the 'Mount' tab selected. The dialog has several tabs: 'Mount', 'Unmount', 'Fsync', 'Mirror', 'Mirror Driver', and 'High Speed SSD'. Under the 'Mount' tab, there are three input fields: 'Mount Option\*' with the value 'rw', 'Timeout\*' with the value '120' and a unit selector set to 'sec', and 'Retry Count\*' with the value '3' and a unit selector set to 'time'. There is an 'Initialize' button on the left and 'OK', 'Cancel', and 'Apply' buttons on the right.

#### Mount Option (Within 1023 bytes)

Enter options to give the mount command when mounting the file system on the mirror partition device. Use a comma "," to separate multiple options.

Mount option example

Setting item	Setting value
Mirror partition device name	/dev/NMP5
Mirror mount point	/mnt/sdb5
File system	ext3
Mount option	rw,data=journal

The mount command to be run with the above settings is:

```
mount -t ext3 -o rw,data=journal /dev/NMP5 /mnt/sdb5
```

#### Timeout (1 to 999)

Enter how many seconds you want to wait for the mount command completion before its timeout when you mount the file system on the mirror partition device. Be careful about the value you specify. That is because it may take some time for the command to complete if the capacity of the file system is large.

#### Retry Count (0 to 999)

Enter how many times you want to retry to mount the file system on the mirror partition device when one fails. If you set this to zero (0), mount will not be retried.

#### Initialize

Clicking **Initialize** resets the values of all items to the default values.

#### Unmount tab

The advanced settings for unmounting are displayed.

This does not appear with **none** selected from **File System** under the **Details** tab of the **Resource Properties** dialog box.

Mirror Disk Resource Tuning Properties

Mount Unmount Fck Mirror Mirror Driver High Speed SSD

Timeout\* 300 sec

Retry Count\* 3 time

Retry Interval\* 5 sec

Forced operation when failure is detected  
☒ Kill  
☐ No Operation

Initialize

OK Cancel Apply

#### Timeout (1 to 999)

Enter how many seconds you want to wait for the unmount command completion before its timeout when you unmount the file system on the mirror partition device.

#### Retry Count (0 to 999)

Enter how many times you want to retry to unmount the file system on the mirror partition device when one fails. If you set this to zero (0), unmount will not be retried.

#### Retry Interval (0 to 999)

Enter the interval in which you want to retry unmounting the file system from the mirror partition device when unmounting fails.

#### Forced operation when failure is detected

Select an action to be taken at an unmount retry if unmount fails.

- kill:  
Select this option to try to forcibly terminate the processes that are accessing the mount point. Not all processes can be terminated.
- No Operation:  
Select this option not to try killing the processes that are accessing the mount point.

#### Initialize

Clicking **Initialize** resets the values of all items to the default values.

#### Fck tab

The advanced settings of fck are displayed.

This does not appear with **xfs** or **none** selected from **File System** under the **Details** tab of the **Resource Properties** dialog box.

Mirror Disk Resource Tuning Properties

Mount Unmount **Fsync** Mirror Mirror Driver High Speed SSD

fsck Option\*

fsck Timeout\*  sec

fsck Action Before Mount

☐ Always Execute

☒ Execute at Specified Count Count\*  time

☐ Not Execute

fsck Action When Mount Failed

Execute ☒

Rebuilding of reiserfs

Execute ☐

**fsck Option** (Within 1023 bytes)

Enter options to give the fsck command when checking the file system on the mirror partition device. Use a space to separate multiple options. Specify options so that the fsck command does not run interactively. Otherwise, activation of resources after the time specified to **fsck Timeout** elapses becomes an error.

**fsck Timeout** (1 to 9999)

Enter how many seconds you want to wait for the fsck command completion before its timeout when you check the file system on the mirror partition device. Be careful about the value you specify. This is because it may take some time for the command to complete if the capacity of the file system is large.

**fsck Action Before Mount**

Select an fsck action before mounting file system on a disk device from the following choices:

- Always Execute:  
fsck is executed before mounting the file system.
- Execute at Specified Count:  
fsck is executed when resource is activated successfully within the count specified by Count.  
= Count (0~999)
- Not Execute:  
fsck is not executed before mounting the file system.

---

**Note:** The specified count for fsck is not related to the check interval managed by a file system.

---

**fsck Action When Mount Failed**

Set an fsck action to take when detecting a mount failure on a disk device.  
This setting is enabled when the setting of Mount **Retry Count** is other than zero.

- When the check box is selected:  
Mount is retried after running fsck.

- When the check box is not selected:  
Mount is retried without running fsck.

---

**Note:** It is not recommended to set "Not Execute" fsck action before performing mount. With this setting, disk resource does not execute fsck and disk resource cannot be failed over when there is an error that can be recovered by fsck in the switchable partition.

---

### Rebuilding of reiserfs

Specify the action when reiserfsck fails with a recoverable error.

- When the checkbox is selected  
reiserfsck --fix-fixable is executed.
- When the checkbox is not selected  
Recovery is not performed even if reiserfsck fails with a recoverable error.

### Initialize

Clicking **Initialize** resets the values of all items to the default values.

### xfs\_repair tab

The detailed settings related to [xfs\_repair] are displayed. The tab appears only if [xfs] is set for the file system.

The screenshot shows a dialog box titled "Mirror Disk Resource Tuning Properties". It has several tabs: "Mount", "Unmount", "xfs\_repair" (which is selected), "Mirror", "Mirror Driver", and "High Speed SSD". The "xfs\_repair" tab contains the following fields and controls:

- xfs\_repair option**: A text input field.
- xfs\_repair Timeout\***: A text input field containing the value "7200", followed by a "sec" label.
- xfs\_repair Action When Mount Failed**: A section with a label "Execute" and an unchecked checkbox.
- Initialize**: A button located at the bottom left of the tab's content area.
- OK**, **Cancel**, and **Apply**: Buttons located at the bottom right of the dialog box.

#### xfs\_repair Option (Within 1023 bytes)

Enter the option to give to the [xfs\_repair] command when checking the file system on the disk device. To enter multiple options, delimit each with a space.

#### xfs\_repair Timeout (1 to 999)

Enter how many seconds you want to wait for the [xfs\_repair] command completion before its timeout when you check the file system on the disk device. If the file system has a large size of disk space, it may take some time for the command to complete. Make sure that the value to set is not too small.

#### xfs\_repair Action When Mount Failed

Set the [xfs\_repair] action when mounting the file system on the disk device fails. This setting is enabled when the setting of **Mount Retry Count** is other than zero.

- When the check box is selected:  
Mount is retried after running [xfs\_repair].
- When the check box is not selected:

Mount is retried without running [xfs\_repair].

### Initialize

Clicking **Initialize** resets the values of all items to the default values.

### Mirror tab

The advanced settings of mirror disks are displayed.

The screenshot shows a dialog box titled "Mirror Disk Resource Tuning Properties". It has several tabs: "Mount", "Unmount", "Fsync", "Mirror" (which is selected), "Mirror Driver", and "High Speed SSD". The "Mirror" tab contains the following settings:

- Execute the initial mirror construction**: ☒
- Execute initial mkfs**: ☒
- Perform Data Synchronization**: ☒
- Mode**:
  - ☒ Synchronous
  - ☐ Asynchronous
- Number of Queues**:
  - ☐ Unlimited
  - ☒ Set Number: 2048
- Limit rate of Mirror Connect**: ☐
- Rate Limit**: 0 KB/sec
- History Files Store Directory**: (empty text box)
- Limit size of History File**: ☐
- Size Limit**: 0 MB
- Compress data**: ☐
- Recovery Method**:
  - Compress data when recovering**: ☐
- Mirror Communication Encryption**:
  - Encrypt mirror communication**: ☐
  - Key File Path**: (empty text box)

At the bottom left is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

### Execute the initial mirror construction

Specify if an initial mirror configuration is constructed when constructing a cluster.

- When the check box is selected:  
An initial mirror configuration will be constructed.

The time that takes to construct the initial mirror is different from ext2/ext3/ext4 and other file systems.

- When the check box is not selected:  
An initial mirror configuration will not be constructed.

### Execute initial mkfs

Specify if an initial mkfs is constructed when constructing a cluster. This option can be set only if the initial mirror is being constructed.

In the case of hybrid disk resources, the clphdinit command behavior is executed instead of initial mkfs behavior upon cluster construction

- When the check box is selected:  
An initial mkfs will be run.
- When the check box is not selected:  
An initial mkfs will not be run.

### Perform Data Synchronization

Specify if the mirror data synchronization is executed when mirror disk resource is activated.

- When the check box is selected:  
Mirror data synchronization is executed. The write data is passed from the active server to the standby server. The clpmdctr command and clphdctrl command can be used not to synchronize mirror data.
- When the check box is not selected:  
Mirror data synchronization will not be executed. The write data will not be passed from the active server to the standby server and will be accumulated as the finite difference. You can use the clpmdctrl command and clphdctrl command to switch to the status where mirror data is synchronized.

### Mode

Specify synchronous mode of mirror data.

- **Synchronous**  
Select when LAN is mainly used for mirror connect.
- **Asynchronous**  
Select when WAN is mainly used for mirror connect. Specify Number of Queues when Asynchronous is chosen. Specify it for each mirror disk resource.
  - Unlimited:  
Queues will be allocated as long as possible to allocate memory. When it failed to allocate memory, mirror breaks.
  - Set Number (1 to 999999):  
Specify maximum number of queues to be allocated. When synchronous data exceeds it, the excess is recorded as a history file.

When **Asynchronous** is selected, the **Rate limitation of Mirror Connect** check box can be selected.

- When the check box is selected (1 to 999999)  
The upper rate limitation of mirror connect is set.
- When the check box is cleared  
The upper rate limitation of mirror connect is not set.

With **Asynchronous** selected, you can edit the setting in the **History File Store Directory** text box to specify the directory of a file in which, if the maximum number of queues is exceeded, the excess is recorded. Without specifying the directory here, the file is generated under the following directory: (EXPRESSCLUSTER-installed directory)/work.

With **Asynchronous** selected, you can edit the setting in the **Size Limitation of History File** text box. When the accumulation in the history file reaches the size specified here, a mirror break occurs. Specifying the value as 0 or nothing makes the size unlimited.

When **Asynchronous** is selected, the **Compress data** check box can be selected.

- When the check box is selected  
Mirror synchronous communication data is compressed.
- When the check box is cleared  
Mirror synchronous communication data is not compressed.

### **Compress data when recovering**

Specify whether to compress mirror recovery communication data.

### **Mirror Communication Encryption**

Choose whether to encrypt data passing through mirror disk connects. This setting affects both data for mirror synchronization and data for mirror recovery.

- If the check box is checked:  
The data is encrypted.
- If the check box is not checked:  
The data is not encrypted.

### **Key File Path (Within 1023 bytes)**

For encrypting data flowing through mirror disk connects, be sure to specify the key file's full path here.

---

#### **Note:**

The key file to be used is generated by using the openssl command of the OS.

The following are examples for RHEL7. For a different distribution, check the openssl command options, which differ from those of RHEL7, before executing the command.

```
# openssl rand 16 -out (key-file name)      Generates a 16-byte (128-bit) encryption key.
# openssl rand 24 -out (key-file name)      Generates a 24-byte (192-bit) encryption key.
# openssl rand 32 -out (key-file name)      Generates a 32-byte (256-bit) encryption key.
```

The applicable key length is 128, 192, or 256 bits.

---

**Important:** Be sure to use the same key file on all servers which can activate mirror disk resources. Using different key files leads to unsuccessful mirroring.

---

### **Initialize**

Clicking **Initialize** resets the values of all items to the default values.

### **Mirror Driver tab**

Advanced settings for a mirror driver is displayed.

Mirror Disk Resource Tuning Properties

Mount Unmount Fsync Mirror Mirror Driver High Speed SSD

Mirror Data Port Number*	29051	
Heartbeat Port Number*	29031	
ACK2 Port Number*	29071	
Send Timeout*	30	sec
Connection Timeout*	10	sec
Ack Timeout*	100	sec
Receive Timeout*	100	sec
Mirror Disk Connect		
Heartbeat interval*	10	sec
ICMP Echo Reply Reception Timeout*	2	sec
ICMP Echo Request Retry Count*	8	time

Initialize

OK Cancel Apply

**Mirror Data Port Number** (1 to 65535<sup>6</sup>)

Set the TCP port number used for sending and receiving disk data between servers. The default value 29051 is set to the mirror disk resource or the hybrid disk resource created first. From a second mirror disk resource or the hybrid disk resource, the value increased by one from default (29052,29053,...) is set accordingly.

**Heartbeat Port Number** (1 to 65535<sup>7</sup>)

Set the port number that a mirror driver uses to communicate control data between servers. The default value 29031 is set to the mirror disk resource or the hybrid disk resource created first. From a second mirror disk resource or the hybrid disk resource, the value increased by one from default (29032, 29033,...) is set accordingly.

**ACK2 Port Number** (1 to 65535<sup>8</sup>)

Set the port number that a mirror driver uses to communicate control data between servers. The default value 29071 is set to the mirror disk resource or the hybrid disk resource created first. From a second mirror disk resource or the hybrid disk resource, the value increased by one from default (29072, 29073,...) is set accordingly.

**Send Timeout** (10 to 99)

Set the delivery time-out for write data.

**Connection Timeout** (5 to 99)

Set the time-out for connection.

**Ack Timeout** (1 to 600)

Set the time-out which waits for Ack response when mirror recovers and data is synchronized.

<sup>6</sup> It is not recommended to use well-known ports, especially reserved ports from 1 to 1023.

<sup>7</sup> It is not recommended to use well-known ports, especially reserved ports from 1 to 1023.

<sup>8</sup> It is not recommended to use well-known ports, especially reserved ports from 1 to 1023.

### **Receive Timeout** (1 to 600)

Set the receive time-out for write confirmation.

### **Heartbeat interval** (1 to 600)

Set the heartbeat interval between mirror disk connects by the mirror driver.

### **ICMP Echo Reply Reception Timeout** (1 to 100)

Set the heartbeat timeout between mirror disk connects by the mirror driver. If no-response is returned for the ICMP Echo Request retry count during the time set here, a mirror disk connect disconnection is assumed.

### **ICMP Echo Request Retry Count** (1 to 50)

Set the heartbeat retry count between mirror disk connects by the mirror driver. This value is related to the mirror connect disconnection judgment sensitivity as well as the ICMP Echo Reply receive timeout.

### **Initialize**

Clicking **Initialize** resets the following values to the default values.

- Send Timeout
- Connection Timeout
- Ack Timeout
- Receive Timeout
- Heartbeat Interval
- ICMP Echo Reply Receive Timeout
- ICMP Echo Request Retry Count

---

**Note:** For **Mirror Data Port Number**, **Heartbeat Port Number** and **ACK2 Port Number**, different port numbers should be configured for each resource. Also, those should not be the same as other port numbers used on a cluster. Thus, the initial values are not set even when you click **Initialize**.

---

### **High Speed SSD tab**

The detailed settings for the high-speed SSD specifications in mirror disk resources are displayed.

Mirror Disk Resource Tuning Properties

Mount Unmount Fsync Mirror Mirror Driver High Speed SSD

**Partition Of The High Speed SSD Use**

Data Partition ☐

Cluster Partition ☐

Initialize

OK Cancel Apply

### **Data Partition**

Select the check box when you use a high-speed SSD for the data partition of mirror disk resources. Make sure that the disk devices used for the data partitions on all nodes are either HDDs or SSDs. If they are used in combination, optimum performance cannot be exerted.

### **Cluster Partition**

Select the check box when you use a high-speed SSD for the cluster partition of mirror disk resources. Make sure that the disk devices used for the cluster partitions on all nodes are either HDDs or SSDs. If they are used in combination, optimum performance cannot be exerted.

## 3.11 Understanding Hybrid disk resources

### 3.11.1 Dependencies of Hybrid disk resource

By default, this function depends on the following group resource types.

Group resource type
Floating IP resource
Virtual IP resource
AWS Elastic IP resource
AWS Virtual IP resource
AWS DNS resource
Azure probe port resource
Azure DNS resource

### 3.11.2 What is hybrid disk?

A hybrid disk is a resource which performs data mirroring between two server groups. A server group consists of 1 server or 2 servers. When a server group consists of 2 servers, a shared disk is used. When a server group consists of 1 server, a disk which is not shared type (e.g. a built-in disk, an external disk chassis which is not shared between servers) is used.

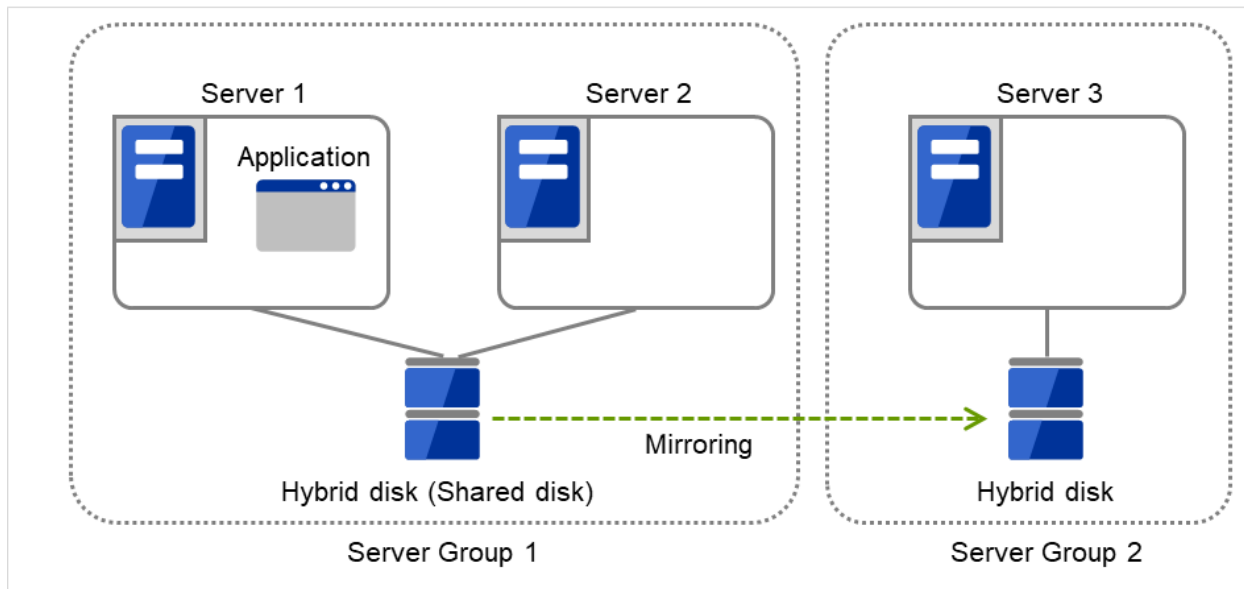

Fig. 3.109: Hybrid configuration (1): in a normal case

When Server 1 crashes, the application is failed over to Server 2.

Fig. 3.110: Hybrid configuration (2): Server 1 crashes

When Server 2 crashes, the application is failed over to Server 3.

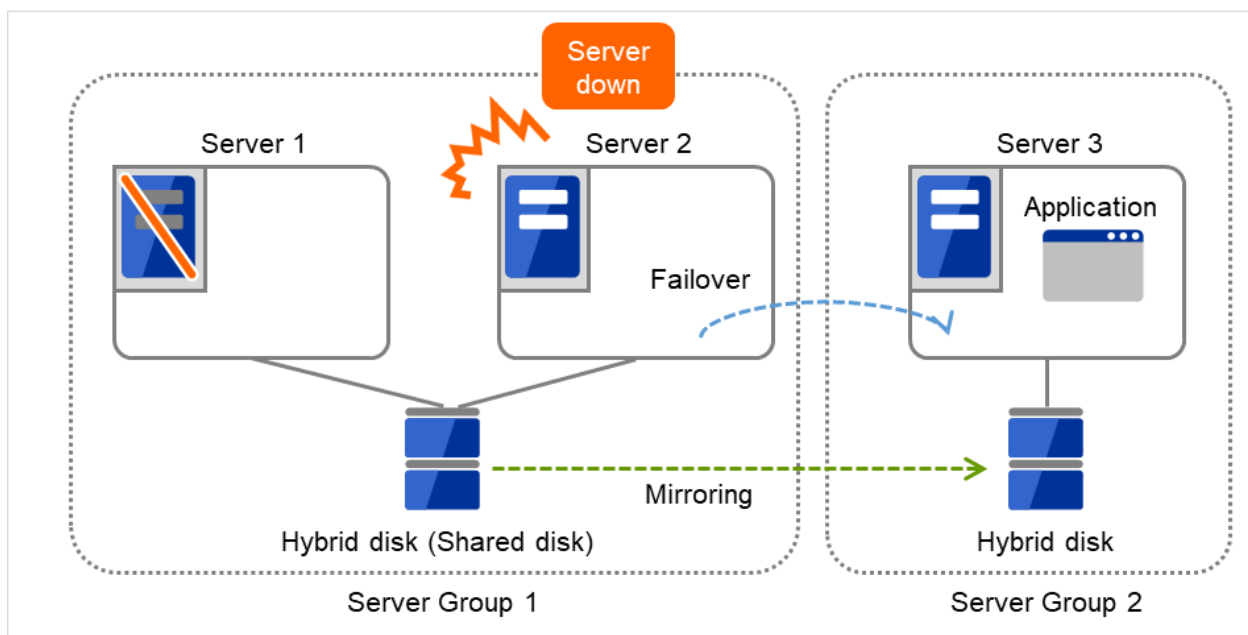

Fig. 3.111: Hybrid configuration (3): Server 2 crashes

### Data partition

Partitions where data to be mirrored (such as application data) is stored are referred to as data partitions.

Allocate data partitions as follows:

- Data partition size  
The size of data partition should be 1GB or larger but smaller than 1TB.  
(Less than 1TB size is recommended from the viewpoint of the construction time and the restoration time of data.)
- Partition ID  
83(Linux)
- Please make the file system on data partitions if you need. Automatic initial mkfs is not executed.
- EXPRESSCLUSTER is responsible for the access control (mount/umount) of file system. Do not configure the settings that allow the OS to mount or unmount a data partition.

### **Cluster partition**

Dedicated partitions used in EXPRESSCLUSTER for controlling hybrid disk are referred to as cluster partition.

Allocate cluster partitions as follows:

- Cluster partition size  
1024MB or more. Depending on the geometry, the size may be larger than 1024MB but that is not a problem.
- Partition ID  
83(Linux)
- A cluster partition and data partition for data mirroring should be allocated in a pair.
- Do not make the file system on cluster partitions.

### **Mirror Partition Device (/dev/NMPx)**

One hybrid disk resource provides the file system of the OS with one mirror partition. If a hybrid disk resource is registered with the failover group, it can be accessed only from one server (it is generally the primary server of the resource group).

Typically, the mirror partition device (dev/NMPx) remains transparent to users (AP) because I/O is performed via a file system. When the information is created by the Cluster WebUI, device names should be assigned without overlapping with each other.

- EXPRESSCLUSTER is responsible for the access control (mount/umount) of file system. Do not configure the settings that allow the OS to mount or unmount a data partition.  
Mirror partition's (hybrid disk resource's) accessibility to applications is the same as switching partition (disk resources) that uses shared disks.
- Mirror partition switching is performed on a failover group basis according to the failover policy.
- /dev/NMPx(x is a number between 1 and 8) is used for the special device name of mirror partition. Do not use /dev/NMPx in other device drivers.
- The major number 218 is used for mirror partition. Do not use the major number 218 in other device drivers.

Example 1) When two servers use the shared disk and the third server uses the built-in disk

The following figure illustrates an example of hybrid configuration: Servers 1 and 2 share a disk, on which the cluster partition's content and the data partition's content are mirrored in a disk connected to Server 3.

The cluster partition and data partition, a unit of failover in a hybrid resource, is a mirror partition device.

Fig. 3.112: Partitions in hybrid configuration

- When a non-shared disk is used (i.e. when there is one server in the server group), it is possible to secure a partition for the hybrid disk resource (cluster partition and data partition) on the same disk where the OS (root partition and swap partition) is located.
  - When maintainability at a failure is important:  
It is recommended to allocate a disk for mirror which is not used by the OS (such as root partition, swap partition).
  - If LUN cannot be added due to H/W RAID specifications:  
If you are using hardware/RAID preinstall model where the LUN configuration cannot be changed, you can allocate a mirror partition (cluster partition, data partition) in the disk where the OS (root partition, swap partition) is located.

#### Mirror disk connect

See "Mirror disk connect" for the *"Mirror disk"*

### 3.11.3 Mirror parameter settings

The following parameters are the same as those of mirror disk resources. See "mirror disk resources".

- Mirror data port number
- Heartbeat port number
- ACK2 port number
- The maximum number of request queues
- Connection timeout
- Send timeout
- Receiving timeout
- Ack timeout
- Difference bitmap update interval (cluster properties)
- Difference Bitmap size (cluster properties)
- Mirror agent send timeout (cluster properties)
- Mirror agent receiving timeout (cluster properties)
- Recovery data size (cluster properties)
- Initial mirror construction
- Number of Queues
- Mode of Communication Band
- History File Store Directory
- Size Limitation of History File
- Heartbeat Interval
- ICMP Echo Reply Receive Timeout
- ICMP Echo Request Retry Count
- Key File Path

The following parameter is different from mirror disk resource.

- Initial mkfs  
Automatic initial mkfs is not executed. Please execute mkfs manually.

### 3.11.4 Notes on hybrid disk resources

- If device names for the cluster partitions or the data partitions differ between servers, set up each server separately. In addition, if the device names differ between servers belonging to the same server group, set by-id to the device name.
- If **Exclude Mount/Unmount Commands** is selected on the **Extension** tab in **Cluster Properties**, activation/deactivation of hybrid disk resource may take time because mount/umount is performed exclusively to disk resource, VxVM volume resource, NAS resource, mirror resource and hybrid disk resource in the same server.
- When specifying path including symbolic link for mount point, Force Operation cannot be done even if it is chosen as operation in failure detection.

Similarly, if a path containing "/" is specified, forced termination will also fail.

- Disks using stripe set, volume set, mirroring, stripe set with parity by Linux md cannot be specified for the cluster partition and data partition.
- Hybrid disk resources (mirror partition devices) cannot be the targets of stripe set, volume set, mirroring, stripe set with parity by Linux md or LVM.
- When the geometries of the disks used as hybrid disks differ between the servers:  
The size of a partition allocated by the fdisk command is aligned by the number of blocks (units) per cylinder. Allocate data partitions to achieve the following data partition size and direction of the initial mirror construction.

**Source server <= Destination server**

"Source server" refers to the server with the higher failover policy in the failover group to which a hybrid disk resource belongs.

"Destination server" refers to the server with the lower failover policy in the failover group to which a hybrid disk resource belongs.

If the data partition sizes differ significantly between the copy source and the copy destination, initial mirror construction may fail. Be careful, therefore, to secure data partitions of similar sizes.

Make sure that the data partition sizes do not cross over 32GiB, 64GiB, 96GiB, and so on (multiples of 32GiB) on the source server and the destination server. For sizes that cross over multiples of 32GiB, initial mirror construction may fail.

Examples)

Combination	Data partition size		Description
	On server 1	On server 2	
OK	30GiB	31GiB	OK because both are in the range of 0 to 32GiB.
OK	50GiB	60GiB	OK because both are in the range of 32GiB to 64GiB.
NG	30GiB	39GiB	Error because they are crossing over 32GiB.
NG	60GiB	70GiB	Error because they are crossing over 64GiB.

- Do not use the O\_DIRECT flag of the open() system call for a file used in a hybrid disk resource. Examples include the Oracle parameter filesystemio\_options = setall.
- Do not specify a mirror partition device (such as /dev/NMP1) as the monitor target in the READ (O\_DIRECT) disk monitoring mode.
- For a cluster configuration that uses a hybrid disk, do not set the final action of a monitor resource, etc., to **Stop the cluster service**.
- For the data partition and the cluster partition of hybrid disk resources, use disk devices with the same logical sector size on all servers. If you use devices with different logical sector sizes, they do not operate normally. They can operate even if they have different sizes for the data partition and the cluster partition.

Examples)

Combination	Logical sector size of the partition				Description
	Server 1	Server 1	Server 2	Server 2	
	Data partition	Cluster partition	Data partition	Cluster partition	
OK	512B	512B	512B	512B	The logical sector sizes are uniform.
OK	4KB	512B	4KB	512B	The data partitions have a uniform size of 4 KB, and the cluster partitions have a uniform size of 512 bytes.
NG	4KB	512B	512B	512B	The logical sector sizes for the data partitions are not uniform.
NG	4KB	4KB	4KB	512B	The logical sector sizes for the cluster partitions are not uniform.

- Do not use HDDs and SSDs in combination for the disks used for the data partition and the cluster partition of hybrid disk resources. If you used them in combination, optimum performance cannot be obtained. Even if disks with different disk types are used for the data partition and the cluster partition, they can operate.

Examples)

Combination	Logical sector size of the partition				Description
	Server 1	Server 1	Server 2	Server 2	
	Data partition	Cluster partition	Data partition	Cluster partition	
OK	HDD	HDD	HDD	HDD	The disk types are uniform.
OK	SSD	HDD	SSD	HDD	The data partitions are of the uniform disk type of SSD, and the cluster partitions are of the uniform type of HDD.
NG	SSD	HDD	HDD	HDD	As the data partitions, both HDD and SSD are used.
NG	SSD	SSD	SSD	HDD	As the cluster partitions, both HDD and SSD are used.

- Behavior of mirror recovery after the active server goes down abnormally

When the active server goes down abnormally, depending on the timing of the server failure, full mirror recovery or differential mirror recovery is performed.

- When a resource is activated by a server connected via a shared disk (a server in the same server group)

The following figure illustrates an example of hybrid configuration: Servers 1 and 2 share a disk, on which the cluster partition's content and the data partition's content are mirrored in a disk connected to Server 3.

Fig. 3.113: Hybrid configuration--resource activation within the same server group (1): in a normal case

When Server 1 crashes, the hybrid disk resource is failed over to Server 2.

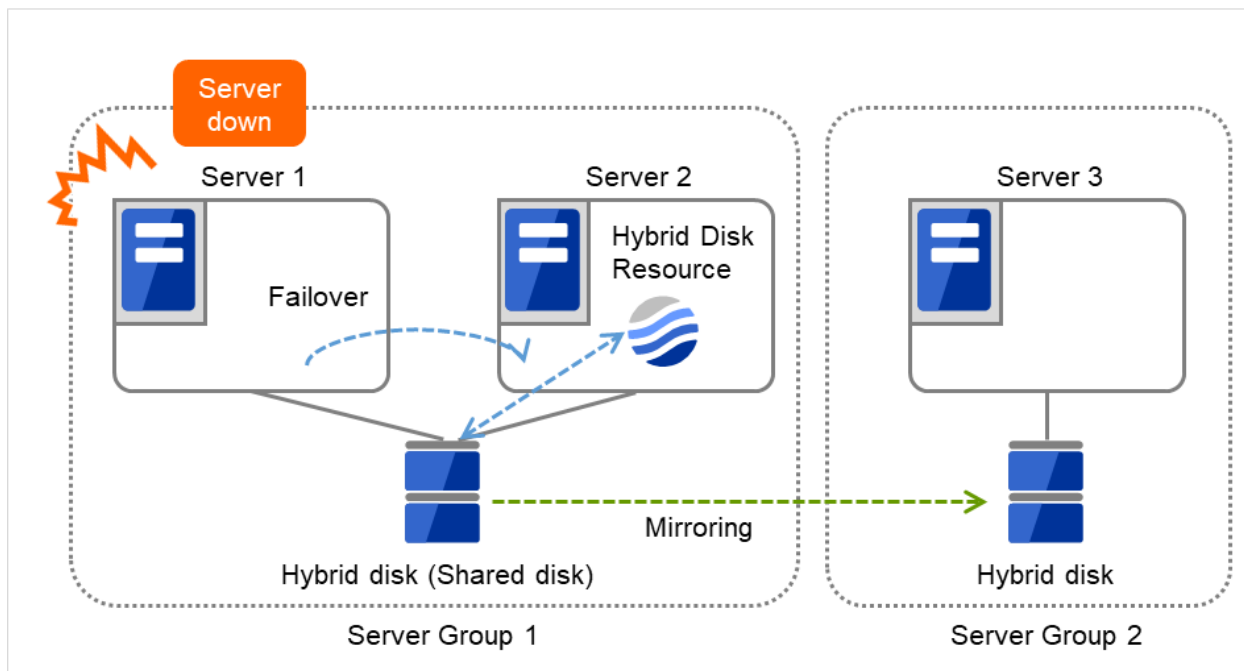

Fig. 3.114: Hybrid configuration--resource activation within the same server group (2): Server 1 crashes

If mirror recovery is required between the shared disk and the Server-3-connected disk, the process varies

depending on when Server 1 crashes:

- a) Just before crashing, Server 1 (active server) recognizes a failure in sending data to Server 3 (standby server), an ACK1 reception error, and succeeds in recording the event in the cluster partition  
Server 2, which belongs to the same server group as that of Server 1, is considered to have the latest data; a full mirror recovery is performed from Server 2 to Server 3.

Fig. 3.115: Hybrid configuration--resource activation within the same server group (3): mirror recovery after Server 1 crashes

- b) For other cases

Since the location of the latest data cannot be ascertained (Server 2 or Server 3), the mirroring is put on hold.

If the failover group's failover attribute is specified as **Automatic failover**, the resource is activated on a next prioritized server after the delayed mirroring.

If the failover group's failover attribute is specified as **Manual failover**, the mirroring is put on hold.

- When a resource is activated by a server in the remote server group

The following figure illustrates an example of hybrid configuration: Servers 1 and 2 share a disk, on which the cluster partition's content and the data partition's content are mirrored in a disk connected to Server 3.

Fig. 3.116: Hybrid configuration--resource activation within the remote server group (1): in a normal case

When Server 1 crashes, the hybrid disk resource is failed over to Server 3.

Fig. 3.117: Hybrid configuration--resource activation within the remote server group (2): Server 1 crashes

- Just before crashing, Server 1 recognizes a failure in sending data to Server 3, an ACK1 reception error, and succeeds in recording the event in the cluster partition

Server group 1 is considered to have the latest data; a failure occurs in activating the group including the hybrid disk resource on Server 3.

Fig. 3.118: Hybrid configuration--resource activation within the remote server group (3): mirror recovery after Server 1 crashes

b) For other cases

Since the location of the latest data cannot be ascertained (Server 2 or Server 3), the mirroring is put on hold.

If the failover group's failover attribute is specified as **Automatic failover**, the resource is activated on a next prioritized server after the delayed mirroring.

If the failover group's failover attribute is specified as **Manual failover**, the mirroring is put on hold.

Fig. 3.119: Hybrid configuration--resource activation within the remote server group (4): mirror recovery after Server 1 crashes

### 3.11.5 mount processing flow

The mount processing needed to activate the hybrid disk resource is performed as follows:

With **none** specified for the file system, the mount processing does not occur.

1. Is the device already mounted?  
When already mounted -> To X
2. Is fsck set to be run before mounting?  
Timing at which to run fsck -> Run fsck for the device.
3. Mount the device.  
Mounted successfully -> To O
4. Is mounting set to be retried?  
When retry is not set -> To X
5. When fsck(xfs\_repair) is set to be run if mounting fails:  
When fsck is executed in 2. and mount is successful -> Go to 6.  
When mount fails in 3. due to a timeout -> Go to 6.  
Other than the above -> Execute fsck(xfs\_repair) for the device.
6. Retry mounting of the device.  
Mounted successfully -> To O
7. Has the retry count for mounting been exceeded?  
Within the retry count -> Go to 6.  
The retry count has been exceeded -> To X

**O** The resource is activated (mounted successfully).

**X** The resource activation has failed (not mounted).

### 3.11.6 umount processing flow

The umount processing to deactivate the hybrid disk resource is performed as follows:

With none specified for the file system, the umount processing does not occur.

1. Is the device already unmounted?

When already unmounted -> To X

2. Unmount the device.

Unmounted successfully -> To O

3. Is unmount set to be retried?

When retry is not set -> To X

4. Is the device still mounted? (Is the mount point removed from the mount list and is the mirror device in the unused status?)

No longer mounted -> To O

5. Try KILL for the process using the mount point.

6. Retry unmount of the device.

Unmounted successfully -> To O

7. Is the result other than the unmount timeout and is the mount point removed from the mount list?

The mount point has already been removed.

-> Wait until the mirror device is no longer used.

(Wait no more than a length of time equal to the unmount timeout.)

8. Has the retry count for unmount been exceeded?

Within the retry count -> Go to 4.

The retry count is exceeded -> To X

**O** The resource is stopped (unmounted successfully).

**X** The resource stop has failed (still mounted, or already unmounted).

### 3.11.7 Details tab

The followings are the same as those of mirror disk resources. Refer to "mirror disk resource".

- Hybrid disk detail tab (See mirror disk detail tab)
- Mirror disk connect selection
- Hybrid disk adjustment properties (See mirror disk adjustment properties)
  - Mount tab
  - Unmount tab
  - Fsync tab

- xfs\_repair tab
- Mirror tab (parameter other than the one for executing the initial mkfs)
- Mirror drive tab
- High-speed SSD tab

The following tab is different from that of mirror disk resource:

- Mirror tab of hybrid disk adjustment properties [execute initial mkfs]

#### **Execute initial mkfs**

The hybrid disk resource in this version, automatic initial mkfs is not executed.

## 3.12 Understanding NAS resource

### 3.12.1 Dependencies of the NAS resource

By default, this function depends on the following group resource type:

Group resource type
Dynamic DNS resource
Floating IP resource
Virtual IP resource
AWS Elastic IP resource
AWS Virtual IP resource
AWS DNS resource
Azure probe port resource
Azure DNS resource

### 3.12.2 NAS resource

- The NAS resource controls the resources in the NFS server.
- By storing the data that is necessary for business transactions in the NFS server, it is automatically passed on when the failover group is moving during failover.

Fig. 3.120: NAS resource (1)

Fig. 3.121: NAS resource (2)

### 3.12.3 Notes on NAS resource

- The EXPRESSCLUSTER will control the access (mount and/or umount) to the file system. Thus, do not configure the settings for the OS to run the mount or umount command.
- On the NFS server, it is necessary to configure the settings that allow servers in the cluster for access to NFS resources.
- On the EXPRESSCLUSTER X, configure the settings that start the portmap service.
- If the host name is specified as the NAS server name, make the settings for name resolving.
- If **Exclude Mount/Unmount Commands** is selected on the **Extension** tab of the **Cluster Properties**, it may take some time to activate or deactivate the NAS resource because the mount or unmount of the disk resource, NAS resource, and mirror resource is performed exclusively in the same server.
- When specifying path including symbolic link for mount point, Force Operation cannot be done even if it is chosen as operation in Detecting Failure.  
Similarly, if a path containing "/" is specified, forced termination will also fail.

### 3.12.4 Details tab

Resource Properties | nas1

nas X

Info Dependency Recovery Operation Details

Server Name\* nfserver1

Shared Name\* /share1

Mount Point\* /mnt/nas1

File System\* nfs

Tuning

OK Cancel Apply

**Server Name** (Within 255 bytes)

Enter the IP address or the server name of the NFS. If you set the host name, set the name resolution to OS. (ex. By adding entry to /etc/hosts)

**Shared Name** (Within 1023 bytes)

Enter the share name on the NFS server.

**Mount Point** (Within 1023 bytes)

Enter the directory where the NFS resource will be mounted. This must start with "/."

**File System** (Within 15 bytes)

Enter the type of file system of the NFS resource. You may also directly enter the type.

- nfs

**Tuning**

Displays the **NAS Resource Tuning Properties** dialog box. Configure the NAS resource detailed settings.

**NAS Resource Tuning Properties****Mount tab**

The advanced settings for mounting are displayed.

**NAS Resource Tuning Properties**

Unmount

NAS

Mount Option\*

rw

Timeout\*

60

sec

Retry Count\*

3

time

Initialize

OK

Cancel

Apply

#### Mount Option (Within 1023 bytes)

Enter the option that is passed to the mount command when mounting a file system. If you are entering more than one option, use "," to separate them.

Examples of the mount option

Setting item	Setting value
Server Name	nfsserver
Shared Name	/share1
Mount Point	/mnt/nas1
File System	nfs
Mount Option	rw

The mount command that is run when the option shown above is set:

```
mount -t nfs -o rw nfsserver1:/share1 /mnt/nas1
```

#### Timeout (1 to 999)

Set the timeout to wait the mount command to be completed when mounting a file system.

It may take a while depending on how heavily network is loaded. Be careful when you are setting the value as the timeout may be detected while a command is running when you set a small value.

#### Retry Count (0 to 999)

Set the number of mount retries when mounting the file system fails.

When zero is set, mounting is not retried.

#### Initialize

Clicking **Initialize** resets the values of all items to the default values.

#### Unmount tab

The advanced settings for unmounting are displayed.

**NAS Resource Tuning Properties**

Mount Unmount **NAS**

**Timeout\*** 120 sec

**Retry Count\*** 3 time

**Retry Interval\*** 5 sec

**Forced operation when failure is detected**

☒ kill

☐ No Operation

Initialize

OK Cancel Apply

**Timeout** (1 to 999)

Set the timeout that waits for the end of the umount command when unmounting a file system.

**Retry Count** (0 to 999)

Set the number of unmount retries to be made when unmounting the file system fails. When zero is set, unmounting is not retried.

**Retry Interval** (0 to 999)

Enter the interval in which you want to retry unmounting the file system when unmounting fails.

**Forced operation when failure is detected**

Select an action to be taken when retrying unmount after unmount fails from the following.

- **kill:**  
Attempts the forceful termination of the process that is accessing the mount point. This does not always mean that the processes can be forcibly terminated.
- **No Operation:**  
Does not attempt the forceful termination of the process that is accessing the mount point.

**Initialize**

Clicking **Initialize** resets the values of all items to the default values.

**NAS tab**

The advanced settings for NAS are displayed.

The screenshot shows a dialog box titled "NAS Resource Tuning Properties". It has three tabs: "Mount", "Unmount", and "NAS", with the "NAS" tab currently selected. Below the tabs, there is a label "ping Timeout\*" followed by a text input field containing the number "10" and the unit "sec". Below the input field is an "Initialize" button. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

**Ping Timeout** (0 to 999)

Set timeout of the ping command is used to check the connection with the server when activating and deactivating NAS resources. If zero is specified, the ping command is not is used.

**Initialize**

Clicking **Initialize** sets all the items to their default values.

## 3.13 Understanding Volume manager resources

### 3.13.1 Dependencies of Volume manager resources

The volume manager resources depend on the following group resource types by default.

Group resource type
Dynamic DNS resource
Floating IP resource
Virtual IP resource
AWS Elastic IP resource
AWS Virtual IP resource
AWS DNS resource
Azure probe port resource
Azure DNS resource

### 3.13.2 What is a Volume manager resource?

- The volume manager is disk management software that handles multiple storage devices and disks as one logical disk.
- Volume manager resources control logical disks managed by the volume manager.
- If data necessary for operation is stored in a logical disk, it is automatically taken over, for example, when there is a failover or a failover group is moved.

Fig. 3.122: Volume manager resource (1)

Fig. 3.123: Volume manager resource (2)

### 3.13.3 Notes on Volume manager resources

#### <General>

- Do not use volume manager resources to manage a mirror disk.
- Disk resources control each volume.
- Do not specify the import or export settings on the OS because EXPRESSCLUSTER performs access control (importing or exporting) for logical disks.

#### <Notes on using resources with the volume manager lvm>

- Volume groups are not defined on the EXPRESSCLUSTER side.
- At least one disk resource is required because each volume must be controlled.
- The volume groups included in the EXPRESSCLUSTER configuration data are automatically exported when the OS is started.
- Other volume groups are not exported.
- When a volume group created by using a shared disk is specified as a target volume, the import/export status of the volume group is recorded on the shared disk according to the LVM specification. Therefore, if activation (import) or deactivation (export) is performed on the active server, it might be assumed that the same operation is performed on the standby server.
- When controlling the LVM by using the volume manager resource in an environment of Red Hat Enterprise Linux 7 or later, the LVM metadata daemon must be disabled.
- Run the following commands when activating resource.

Command	Option	Timing when using command
vgs	-P	Verifying volume group status
	--noheadings	Verifying volume group status
	-o vg_attr,vg_name	Verifying volume group status
vgimport	(Nothing)	Importing volume group
vgscan	(Nothing)	Scanning volume group
vgchange	-ay	Activating volume group

- The resource activation sequence is shown below.

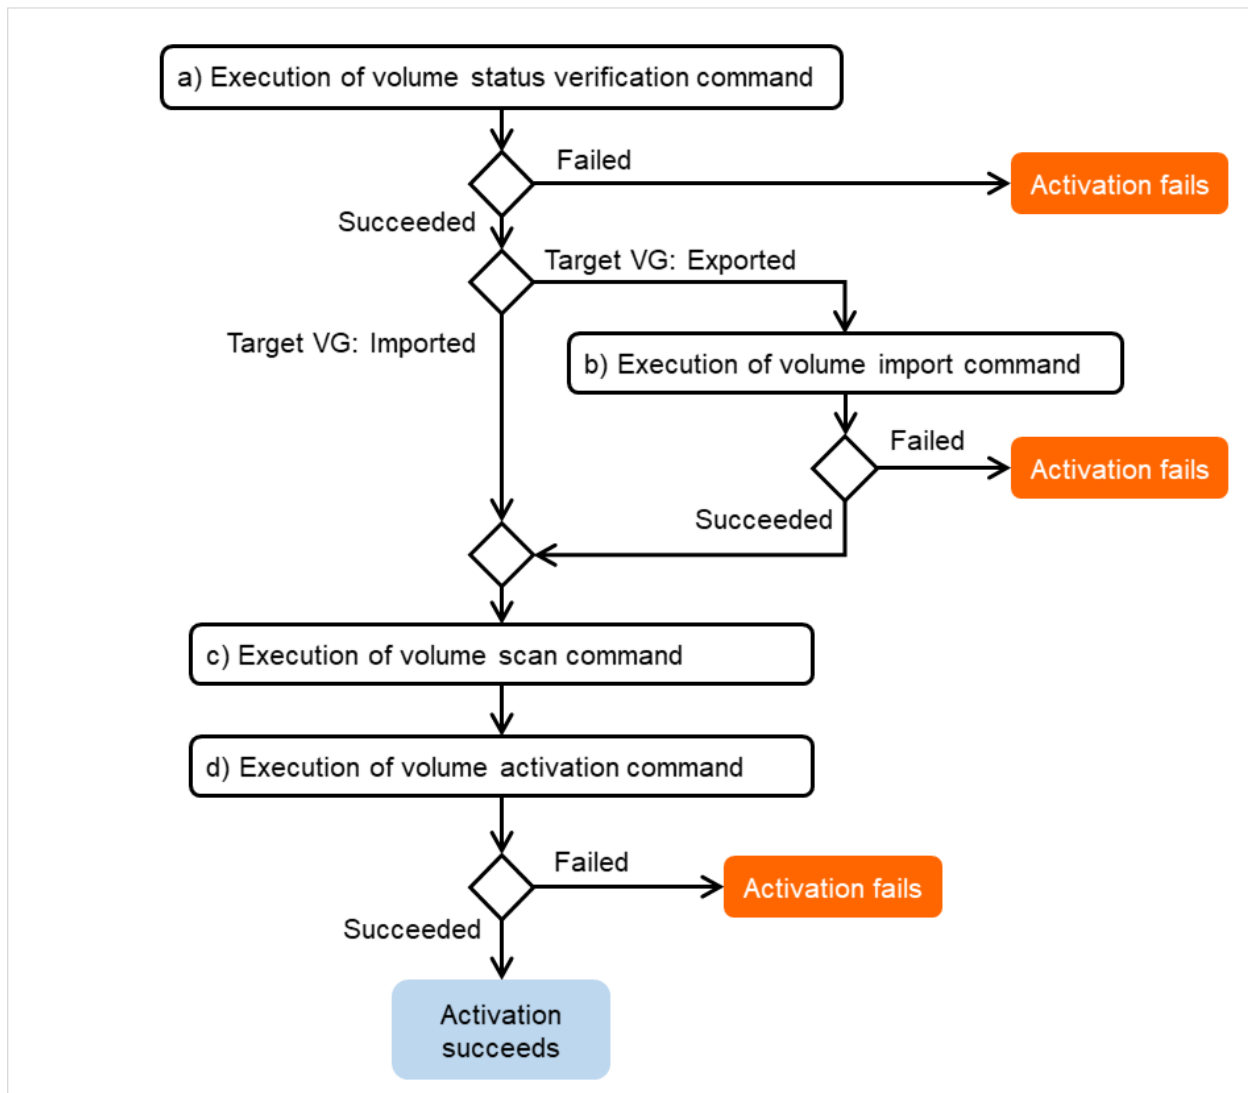

Fig. 3.124: Resource activation sequence (lvm)

- a) Perform the command for verifying the volume group status. Its failure means that in the activation.

```
vgs -P --noheadings -o vg_attr, vg_name Volume group name
```

- b) Perform the command for importing the volume group. Its failure means that in the activation.

```
vgimport Volume group name
```

c) Perform the command for scanning the volume group.

```
vgscan
```

d) Perform the command for activating the volume group. Its success means that in the activation; its failure means that in the activation.

```
vgchange -ay Volume group name
```

- Run the following commands when deactivating resource.

Command	Option	Timing when using command
vgs	-P	Verifying volume group status
	--noheadings	Verifying volume group status
	-o vg_attr,vg_name	Verifying volume group status
vgchange	-an	Deactivating volume group
vgexport	(Nothing)	Exporting volume group

- The resource deactivation sequence is shown below.

Fig. 3.125: Resource deactivation sequence (lvm)

a) Perform the command for verifying the volume group status. Its failure means that in the deactivation.

The success in the execution means that in the deactivation, if the target volume group is found ready for export .

```
vgs -P --noheadings -o vg_attr, vg_name Volume group name
```

- b) Perform the command for deactivating the volume group. Its failure means that in the deactivation.

```
vgchange -an Volume group name
```

- c) Perform the command for exporting the volume group. Its success means that in the deactivation; its failure means that in the deactivation.

```
vgexport Volume group name
```

#### <Notes on using resources with the volume manager vxvm>

- Disk groups are not defined on the EXPRESSCLUSTER side.
- The disk groups included in the EXPRESSCLUSTER configuration data are automatically deported when the OS is started.
- Other disk groups are not deported.
- If the **Clear host ID** option is not selected, disk groups cannot be imported to the failover destination server due to VxVM specifications if the failover source server fails to normally deport the disk groups.
- Even if an import timeout occurs, importing might be successfully completed. This problem can be avoided by specifying the **Clear host ID** or **Forced Option at Import** option, which retries importing.
- Run the following commands when activating a resource.

Command	Option	When to use
vx dg	import	When importing a disk group
	-t	When importing a disk group
	-C	When importing a disk group fails and the <b>Clear host ID</b> option is selected
	-f	When importing a disk group fails and the <b>Forced Activation</b> option is selected
vx recover	-g	When the volume for the specified disk group is started
	-sb	When the volume for the specified disk group is started

- The resource activation sequence is shown below.

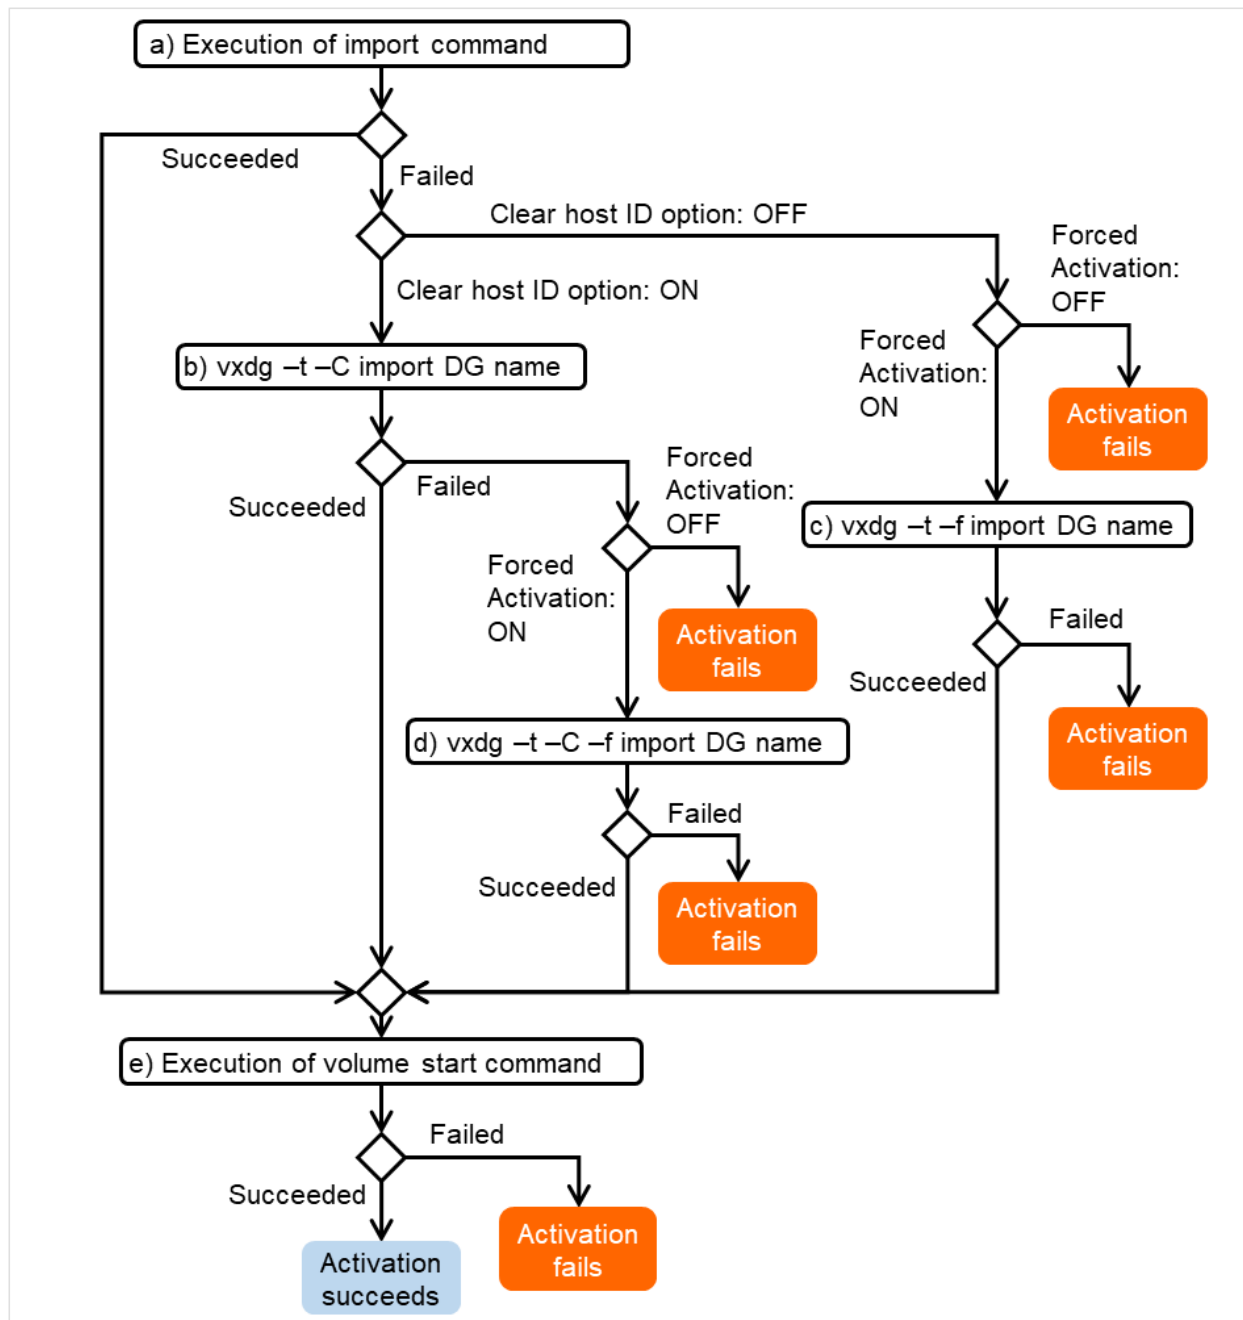

Fig. 3.126: Resource activation sequence (vxvm)

a) Perform the import command. Its failure means that in the activation.

```
vxldg -t import Disk group name
```

b) Perform the following command:

```
vxldg -t -C import Disk group name
```

c) Perform the following command:

```
vxldg -t -f import Disk group name
```

d) Perform the following command:

```
vxvg -t -C -f import Disk group name
```

- Run the following commands when activating a resource.

Command	Option	When to use
vxvg	deport	When deporting a disk group
	flush	When flushing data
vxvol	-g	When the volume of the specified disk group is stopped
	stopall	When the volume of the specified disk group is stopped

- The resource deactivation sequence is shown below.

Fig. 3.127: Resource deactivation sequence (vxvm)

- a) Perform the command for stopping the volume.
- b) Perform the flush command.
- c) Perform the deporting command.

**<Notes on using resources with the volume manager zfspool>**

- Exporting and other processes for ZFS may be delayed dramatically if iSCSI connection is disconnected when using ZFS storage pool under iSCSI environment.(OS restriction)  
The ZFS operations at the time of iSCSI disconnection is regulated in ZFS property value **failmode**. However, **failmode=panic** is recommended in EXPRESSCLUSTER. When it is **failmode=panic**, it operates as OS panics independently in a given time after iSCSI
- On the data set that the ZFS property value **mountpoint** is configured in legacy, the file system will not be mounted by just importing the storage pool. In this case, it is necessary to mount or unmount ZFS file system by using the disk resource in addition to Volume Manager resource.
- When on Ubuntu 16.04 or later, a failover group may be activated on more than 1 servers, state of "network partition" in other words, depending on the timing of OS startup. Even if the storage pool is automatically imported at OS startup, prevent the file system from being automatically mounted.  
The way to avoid automatic mounting is either of the below.
  - Set ZFS property value mountpoint to legacy.
  - Set ZFS property value canmount to noauto.

This setting enables to avoid the automatic mounting even when the automatic import is performed at OS startup, preventing the network partition. In this case, it is necessary to mount or unmount ZFS file system by using the disk resource.

### 3.13.4 Details tab

The screenshot shows a window titled "Resource Properties | volmgr1" with a close button "X". Inside, there are four tabs: "Info", "Dependency", "Recovery Operation", and "Details" (which is selected). Below the tabs, there are two labeled fields: "Volume Manager\*" with a dropdown menu showing "lvm", and "Target Name\*" with a dropdown menu showing "vg1". Below these fields is a button labeled "Tuning". At the bottom right of the window are three buttons: "OK", "Cancel", and "Apply".

#### Volume Manager

Specify the volume manager to use. The following volume managers can be selected:

- lvm (LVM volume group control)
- vxvm (VxVM disk group control)
- zfspool (ZFS storage pool control)

#### Target Name (within 1023 bytes)

Specify the volume name in the <VG name> format (only the target name is used).

Combo box options collect volume group information from all the servers and display all the volume groups on one or more servers.

When the volume manager is lvm, it's possible to control multiple volumes together. More than one volume is delimited with an one-byte space.

#### Tuning

This displays the **Volume Manager Resource Tuning Properties** dialog box. Specify detailed settings for the volume manager resource.

#### Volume Manager Resource Tuning Properties (When Volume Manager is other than [zfspool])

#### Import Tab

The detailed import settings are displayed.

The dialog box is titled "Volume Manager Resource Tuning Properties". It has two tabs: "Import" (selected) and "Export". Under the "Import" tab, there are three input fields with labels and units: "Import Timeout\*" (300 sec), "Start Volume Timeout\*" (60 sec), and "Volume Status Check Timeout\*" (60 sec). Below these are two checkboxes: "Clear Host ID" and "Forced Import", both of which are checked. At the bottom left is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

**Import Timeout** (1 to 9999)

Specify how long the system waits for completion of the volume import command before it times out.

**Start Volume Timeout** (1 to 9999)

Specify the startup command timeout.

**Volume Status Check Timeout** (1 to 9999)

Specify the volume status check command timeout.

This option can be used when the volume manager is **lvm**.

**Clear Host ID**

When normal importing fails, the clear host ID flag is set and importing is retried. The host ID is cleared when the check box is selected.

This option can be used when the volume manager is **vxvm**.

**Forced Import**

Specify whether to forcibly import data when importing fails. Data is forcibly imported if the check box is selected.

This option can be used when the volume manager is **vxvm**.

**Initialize**

Clicking **Initialize** resets the values of all items to the defaults.

**Export Tab**

The detailed export settings are displayed.

The dialog box is titled "Volume Manager Resource Tuning Properties". It has two tabs: "Import" (selected) and "Export". Below the tabs, there are four rows of settings, each with a label, a text input field, and a unit. The first row is "Stop Volume Timeout\*" with a value of 60 and unit "sec". The second row is "Flush Timeout" with a value of 60 and unit "sec". The third row is "Export Timeout\*" with a value of 300 and unit "sec". The fourth row is "Volume Status Check Timeout\*" with a value of 60 and unit "sec". Below these settings is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

Property	Value	Unit
Stop Volume Timeout*	60	sec
Flush Timeout	60	sec
Export Timeout*	300	sec
Volume Status Check Timeout*	60	sec

**Stop Volume Timeout** (1 to 9999)

Specify the volume deactivation command timeout.

**Flush Timeout** (1 to 9999)

Specify the flush command timeout.

This option can be used when the volume manager is **vxvm**.

**Export Timeout** (1 to 9999)

Specify the export/deport command timeout.

**Volume Status Check Timeout** (1 to 9999)

Specify the volume status check command timeout.

This option can be used when the volume manager is **lvm**.

**Initialize**

Clicking **Initialize** resets the values of all items to the defaults.

**Volume Manager Resource Tuning Properties (When Volume Manager is [zfspool])****Import Tab**

The detailed import settings are displayed.

The dialog box is titled "Volume Manager Resource Tuning Properties". It has two tabs: "Import" (selected) and "Export". Under the "Import" tab, there are three settings: "Import Timeout\*" with a text box containing "300" and "sec" to its right; "Forced Import" with a checked checkbox; and "Execute Ping Check" with a checked checkbox. Below these settings is an "Initialize" button. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

**Import Timeout** (1 to 9999)

Specify how long the system waits for completion of the volume import command before it times out.

**Forced Import**

Specify whether to forcibly import data when importing fails. Data is forcibly imported if the check box is selected.

**Execute Ping Check**

This setting is enabled only when **Forced Import** is set to ON.

If an import failure occurs because another host has already performed import, **ping Check** specifies monitoring of whether the host is active using ping before the forced import. If the host becomes active as a result of the monitoring, forced activation is not performed. This prevents more than one host from simultaneously performing import to a single pool. When the check box is ON, activation of the host is monitored.

---

**Note:** When this setting is enabled, and a considerable time elapses between EXPRESS-CLUSTER stopping and the OS shutting down, failover may fail. For example, if a monitor resource detects an abnormality and shuts down the operating server, and if the standby system starts activation of the volume manager before the operating server has stopped, a ping check will cause the activation to fail.

---

**Initialize**

Clicking **Initialize** resets the values of all items to the defaults.

**Export Tab**

The detailed export settings are displayed.

The dialog box is titled "Volume Manager Resource Tuning Properties". It features two tabs: "Import" and "Export", with "Export" currently selected. Below the tabs, there are three main settings: "Export Timeout\*" with a text input field containing "300" and a "sec" label; "Forced Export" with a checked checkbox; and an "Initialize" button. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

**Export Timeout (1 to 9999)**

Specify how long the system waits for completion of the volume export command before it times out.

**Forced Export**

Specify whether to forcibly export data when exporting fails. Data is forcibly exported if the check box is selected.

**Initialize**

Clicking **Initialize** resets the values of all items to the defaults.

## 3.14 Understanding VM resources

### 3.14.1 Dependencies of VM resources

VM resources do not depend on any group resource type by default.

### 3.14.2 What is a VM resource?

The VM resources control the virtual machines (guest OSs) in the virtualization infrastructure.

The management OS under which EXPRESSCLUSTER is installed starts and stops the virtual machines. For vSphere, EXPRESSCLUSTER can be installed and used under the guest OS of the virtual machine which was prepared for management.

Migration of the virtual machines can also be performed. If, however, vSphere is used, the configuration must also use vCenter.

Fig. 3.128: Configuration when EXPRESSCLUSTER is installed under the management OS for the virtualization infrastructure

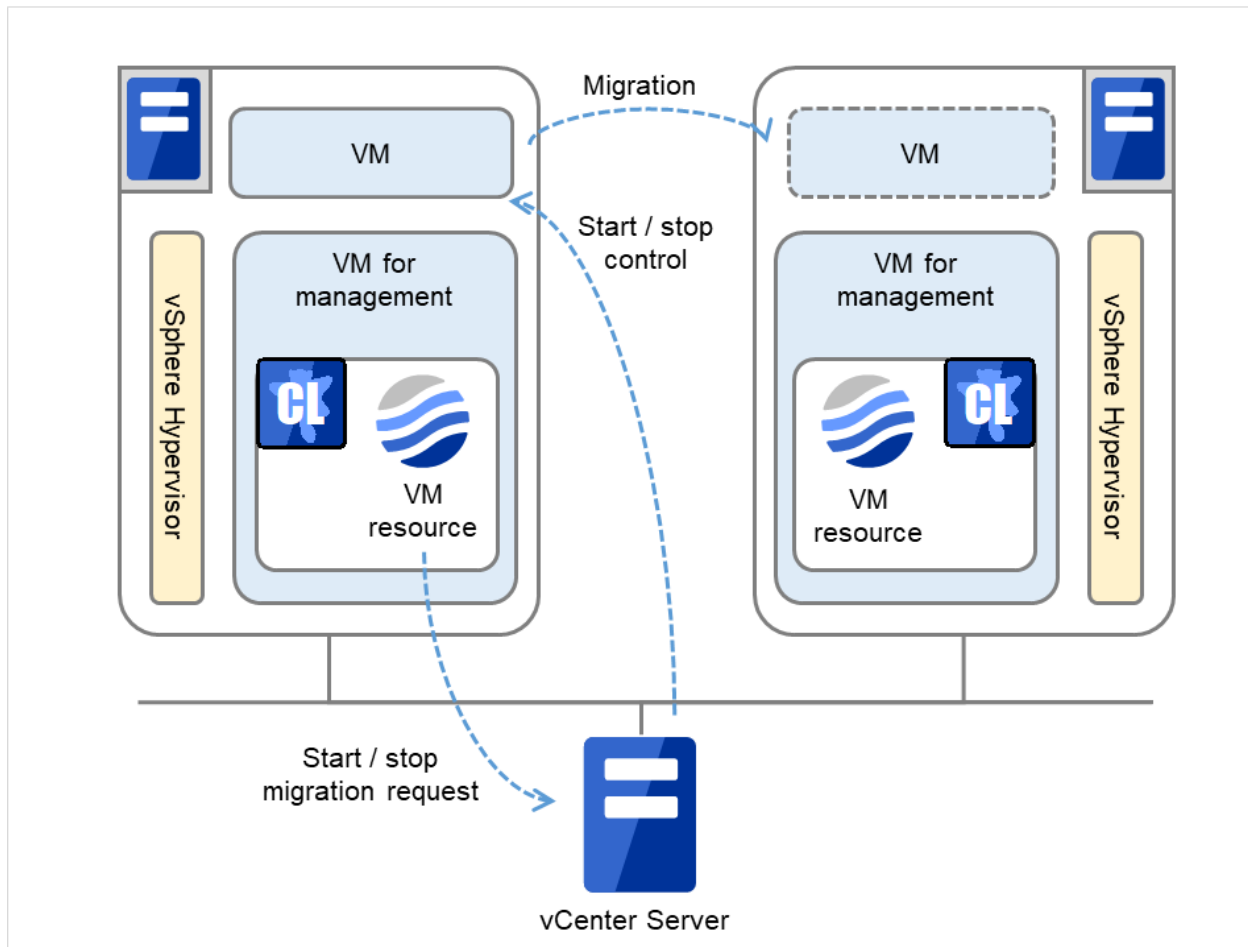

Fig. 3.129: Configuration when EXPRESSCLUSTER is installed under the OS on a virtual machine for management (vSphere only)

### 3.14.3 Notes on VM resources

- If the virtualization infrastructure type is XenServer or KVM, the VM resources are valid only when EXPRESSCLUSTER is installed under the host OS in the virtualization infrastructure.
- If the virtualization infrastructure type is vSphere, the VM resources can be used even if EXPRESSCLUSTER is installed under the guest OS. In this case, however, vCenter must always be used.
- A VM resource can be registered with a group for which the group type is virtual machine.
- Only one VM resource can be registered per group.
- If vSphere is selected as the virtualization infrastructure, **Use vCenter** must be selected (on) to perform migration.
- Confirm the start time of the virtual machine (guest OS) to be controlled with a virtual machine resource, and set **Virtual Machine Start Wait Time** of **Virtual Machine Resource Adjustment Property**.  
The default value of **Virtual Machine Start Wait Time** is 0 seconds, so if it is not changed, the virtual machine monitor resource may mistakenly detect a monitor error.

Specify the virtualization infrastructure type.

### Virtual Machine Name (within 255 bytes)

Enter the virtual machine name. This setting is not required if the UUID is specified. Specify the UUID if the virtual machine name might be changed in the virtualization infrastructure.

### UUID

Specify the UUID (Universally Unique Identifier) for identifying the virtual machine.

### Library Path (within 1,023 bytes)

Specify the library path used to control XenServer.

### User Name (within 255 bytes)

Specify the user name used to start the virtual machine.

### Password (within 255 bytes)

Specify the password used to start the virtual machine.

VM Resource Tuning Properties

**Virtual Machine Resource Tuning Properties**

Parameter

<b>Request Timeout*</b>	<input type="text" value="30"/>	sec
<b>Virtual Machine Start Waiting Time*</b>	<input type="text" value="0"/>	sec
<b>Virtual Machine Stop Waiting Time*</b>	<input type="text" value="240"/>	sec

Initialize

OK

Cancel

Apply

#### **Request Timeout**

Specify how long the system waits for completion of a request such as to start or stop a virtual machine.

If the request is not completed within this time, a timeout occurs and resource activation or deactivation fails.

#### **Virtual Machine Start Waiting Time**

The system definitely waits this time after requesting the virtual machine to startup.

#### **Virtual Machine Stop Waiting Time**

The maximum time to wait for the stop of the virtual machine. Deactivation completes at the timing the stop of the virtual machine.

## 3.15 Understanding Dynamic DNS resources

### 3.15.1 Dependencies of Dynamic DNS resources

By default, NAS resources depend on the following group resources types:

Group resource type
Virtual IP resource
Floating IP resource
AWS Elastic IP resource
AWS Virtual IP resource
Azure probe port resource

### 3.15.2 What is a Dynamic DNS resource?

- A Dynamic DNS resource registers the virtual host name and the IP address of the active server to the Dynamic DNS server. Client applications can be connected to a cluster server by using a virtual computer name. When the virtual host name is used, the client does not have to be aware of whether the connection destination server is switched when a failover occurs or a group is moved.

The following figure shows the Dynamic DNS server (DDNS server), Servers 1 and 2, and a client. On the DDNS server, Server 1 registers the virtual host name and the IP address.

Fig. 3.130: Configuration with the DDNS server (1)

The client queries the DDNS server about the IP address (corresponding to the virtual host name) to be accessed. The DDNS server returns the IP address (corresponding to the virtual host name) of Server 1 to the client. The client then accesses the IP address of the virtual host name.

Fig. 3.131: Configuration with the DDNS server (2)

Server 1 crashes, and a failover to Server 2 occurs.

Fig. 3.132: Configuration with the DDNS server (3)

On the DDNS server, Server 2 registers the virtual host name and the IP address.

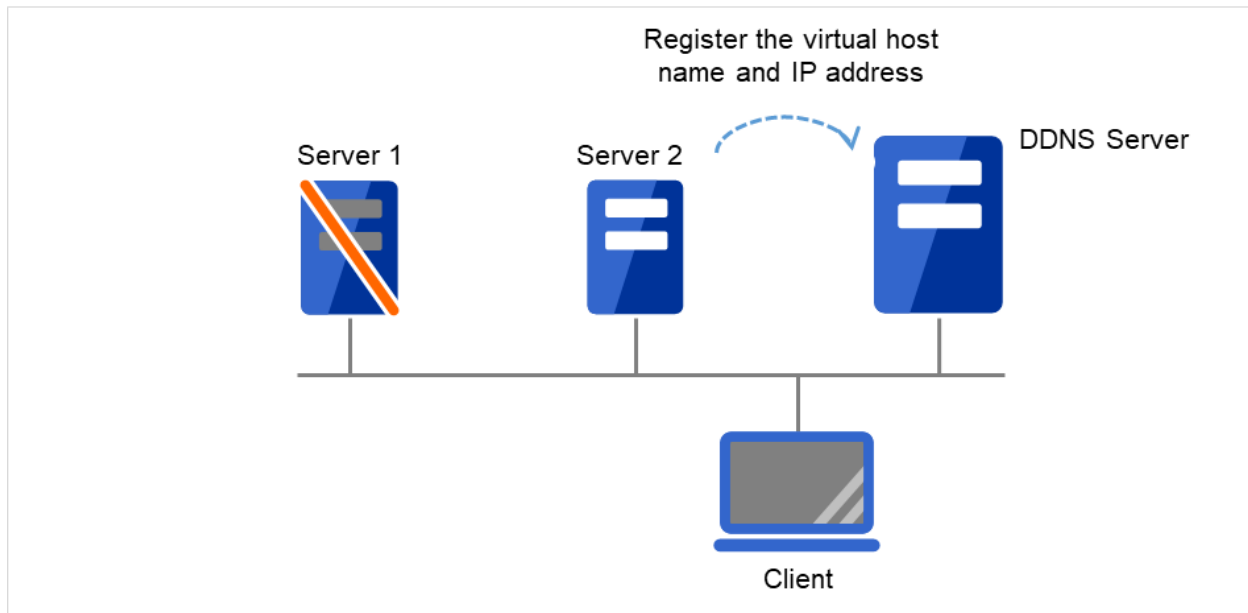

Fig. 3.133: Configuration with the DDNS server (4)

The client queries the DDNS server about the IP address (corresponding to the virtual host name) to be accessed. The DDNS server returns the IP address (corresponding to the virtual host name) of Server 2 to the client. The client then accesses the IP address of the virtual host name.

Fig. 3.134: Configuration with the DDNS server (5)

### 3.15.3 Preparing to use Dynamic DNS resources

Set up the DDNS server before using Dynamic DNS resources.

The description below assumes the use of BIND9.

One of the two types of `/etc/named.conf` settings below is used depending on the Dynamic DNS resource use mode when the DDNS server is set up.

Specify `/etc/named.conf` on the DDNS server in the desired mode.

- When using Dynamic DNS resources with authentication

Create a shared key on the BIND9 server by using the `dnssec-keygen` command. Add the shared key to `/etc/named.conf` and allow the zone file to be updated. When adding a Dynamic DNS resource, enter the shared key name in **Authentication Key Name** and the shared key value in **Authentication Key Value**.

---

**Note:** For details about setting up the DDNS server, using the `dnssec-keygen` command, and specifying setting other than `allow-update`, see the BIND manual.

---

Example:

1. **Generate a shared key.**

```
#dnssec-keygen -a HMAC-MD5 -b 256 -n HOST example
```

example is the shared key name.

When the `dnssec-keygen` command is executed, the two files below are generated. The same shared key is used for these files.

```
Kexample.+157+09088.key
Kexample.+157+09088.private
```

While the shared key is extracted from `Kexample.+157+09088.key` when using the `named.conf` setting below, using `Kexample.+157+09088.private` leads to the same result.

The shared key value for `Kexample.+157+09088.key` is underlined below.

```
# cat Kexample.+157+09088.key
example. IN KEY 512 3 157 iuBgSUEIBjQUKNJ36NocAgaB
```

2. Add the shared key information to `/etc/named.conf`.

```
key " example " {
    algorithm hmac-md5;
    secret " iuBgSUEIBjQUKNJ36NocAgaB";
};
```

3. Add the shared key information to the zone statement in /etc/named.conf.

```
zone "example.jp" {  
    :  
    allow-update {  
        key example;  
    };  
    :  
};
```

4. When adding a Dynamic DNS resource by using the Cluster WebUI, enter the shared key name (**example**) in **Authentication Key Name** and the shared key value (**iuBgSUEIBjQUKNJ36NocAgaB**) in **Authentication Key Value**.

- When using Dynamic DNS resources without authentication

Be sure to specify the IP addresses of all servers in the cluster as the IP address range in which the zone file can be updated (allow-update {xxx.xxx.xxx.xxx}) in /etc/named.conf.

Example:

IP address for Server 1 in the cluster: 192.168.10.110

IP address for Server 2 in the cluster: 192.168.10.111

1. Add the IP address range in which updates are allowed to the zone statement in /etc/named.conf.

```
zone "example.jp" {  
    :  
    //IP address range in which updates are allowed  
    allow-update {  
        192.168.10.0/24;  
    };  
    :  
};
```

or

```
zone "example.jp" {  
    :  
    //IP address range in which updates are allowed  
    allow-update {  
        192.168.10.110;  
        192.168.10.111;  
    };  
    :  
};
```

2. When adding a Dynamic DNS resource, do not enter any values in **Authentication Key Name** or **Authentication Key Value**.

### 3.15.4 Notes on Dynamic DNS resources

- When using Dynamic DNS resources, the bind-utils package is necessary on each server.
- Configuring Dynamic DNS server settings to be used is necessary to /etc/resolve.conf on each server.
- When IP address of each server exists in different segments, FIP address cannot be set as IP address of Dynamic DNS resources.
- To register each server IP address with the DDNS server, specify the addresses in the settings for each server.
- In case of connecting from clients using virtual host name, when the fail over of the group which has Dynamic DNS resources occurs, reconnection may be necessary (restart browsers, etc.).
- This method, which authenticates resources, applies only to a DDNS server set up using BIND9. To use the method without authentication, do not enter any values in **Authentication Key Name** or **Authentication Key Value**.
- The behavior when the Cluster WebUI is connected depends on the Dynamic DNS resource settings.
  - When the IP address of each server is specified for Dynamic DNS resources on a server basis  
If the Cluster WebUI is connected by using the virtual host name from the client, this connection is not automatically switched if a failover occurs for a group containing Dynamic DNS resources.  
To switch the connection, restart the browser, and then connect to the Cluster WebUI again.
  - When the FIP address is specified for the Dynamic DNS resource  
If the Cluster WebUI is connected by using the virtual host name from the client, this connection is automatically switched if a failover occurs for a group containing Dynamic DNS resources.
- If Dynamic DNS resources are used with the method with authentication, the difference between the time of every server in the cluster and that of the DDNS server must be less than five minutes.  
If the time difference is five minutes or more, the virtual host name cannot be registered with the DDNS server.

### 3.15.5 Details tab

#### Virtual Host Name

Enter the virtual host name to register with the DDNS service.

#### **IP Address** Server Individual Setup

Enter the IP address for the virtual host name.

When also using FIP resources, enter the IP address of the resources on the **Common** tab.

When using an IP address for each server, enter the IP address on each server tab.

#### **DDNS Server**

Enter the IP address of the DDNS server.

#### **Port No.**

Enter the port number of the DDNS server. The default value is 53.

#### **Authentication Key Name**

Enter the shared key name if a shared key was generated using the dnssec-keygen command.

#### **Authentication Key Value**

Enter the value of the shared key generated using the dnssec-keygen command.

## **3.16 Understanding AWS Elastic IP resources**

### **3.16.1 Dependencies of AWS Elastic IP resources**

By default, this function does not depend on any group resource type.

### **3.16.2 What is an AWS Elastic IP resource?**

Client applications can use AWS Elastic IP addresses(referred to as the EIP) to access the Amazon Virtual Private Cloud (referred to as the VPC) in the Amazon Web Services (referred to as AWS) environment.

By using EIP, clients do not need to be aware of switching access destination server when a failover occurs or moving a group migration.

An AWS Elastic IP resource, an AWS Virtual IP resource, and an AWS DNS resource can be used together.

#### **HA cluster with EIP control**

This is used to place instances on public subnets (release business operations inside the VPC).

A configuration such as the following is assumed: Instances to be clustered are placed on public subnets in each Availability Zone (referred to as AZ), and each instance can access the Internet via the gateway.

Fig. 3.135: Configuration with an AWS Elastic IP resource

### 3.16.3 Notes on AWS Elastic IP resources

- See "Setting up AWS Elastic IP resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

### 3.16.4 Applying environment variables to AWS CLI run from the AWS Elastic IP resource

Specify environment variables in the environment variable configuration file to apply environment variables to the AWS CLI run from the AWS Elastic IP resource, AWS Virtual IP resource, AWS Elastic IP monitor resource and AWS AZ monitor resource.

This feature is useful when using a proxy server in an AWS environment.

The environment variable configuration file is stored in the following location.

<EXPRESSCLUSTER Installation path>/cloud/aws/clpaws\_setting.conf

The format of the environment variable configuration file is as follows:

Environment variable name = Value

(Example)

```
[ENVIRONMENT]
HTTP_PROXY = http://10.0.0.1:3128
HTTPS_PROXY = http://10.0.0.1:3128
```

To specify multiple values for a parameter, enter them in comma-delimited format. The following shows an example of specifying more than one non-destination for the environment variable NO\_PROXY:

(Example)

```
NO_PROXY = 169.254.169.254,ec2.ap-northeast-1.amazonaws.com
```

The specifications of the environment variable configuration file are as follows:

- Write [ENVIRONMENT] on the first line. If this is not set, the environment variables will not be set.
- If the environment variable configuration file does not exist or you do not have read permission for the file, the variables are ignored. This does not cause an activation failure or a monitor error.
- If the same environment variables already exist in the file, the values are overwritten.
- More than one environment variable can be set. Set one environment variable on each line.
- The settings are valid regardless of whether there are spaces before and after "=" or not.
- The settings are invalid if there is a space or tab in front of the environment variable name or if there are tabs before and after "=".
- Environment variable names are case sensitive.
- Even if a value contains spaces, you do not have to enclose the value in "" (double quotation marks).
- The environment variables configured with the environment variable configuration file are propagated only to the AWS CLI executed from an AWS Elastic IP resource, an AWS Virtual IP resource, an AWS DNS resource, an AWS Elastic IP monitor resource, an AWS Virtual IP monitor resource, an AWS DNS monitor resource, and an AWS AZ monitor resource. Therefore, the configured variables are not propagated to any other script (e.g. a script before final action, a script before and after activation/deactivation, and a script to be run from EXEC resources). To execute the AWS CLI with such a script, configure necessary environment variables with the corresponding script.

### 3.17.4 Applying environment variables to AWS CLI run from the AWS Virtual IP resource

Specify environment variables in the environment variable configuration file to apply environment variables to the AWS CLI run from the AWS Elastic IP resource, AWS Virtual IP resource, AWS Elastic IP monitor resource and AWS AZ monitor resource.

This feature is useful when using a proxy server in an AWS environment.

The environment variable configuration file is stored in the following location.

<EXPRESSCLUSTER Installation path>/cloud/aws/clpaws\_setting.conf

The format of the environment variable configuration file is as follows:

Environment variable name = Value

(Example)

```
[ENVIRONMENT]
HTTP_PROXY = http://10.0.0.1:3128
HTTPS_PROXY = http://10.0.0.1:3128
```

To specify multiple values for a parameter, enter them in comma-delimited format. The following shows an example of specifying more than one non-destination for the environment variable NO\_PROXY:

(Example)

```
NO_PROXY = 169.254.169.254,ec2.ap-northeast-1.amazonaws.com
```

The specifications of the environment variable configuration file are as follows:

- Write [ENVIRONMENT] on the first line. If this is not set, the environment variables will not be set.
- If the environment variable configuration file does not exist or you do not have read permission for the file, the variables are ignored. This does not cause an activation failure or a monitor error.
- If the same environment variables already exist in the file, the values are overwritten.
- More than one environment variable can be set. Set one environment variable on each line.
- The settings are valid regardless of whether there are spaces before and after "=" or not.
- The settings are invalid if there is a space or tab in front of the environment variable name or if there are tabs before and after "=".
- Environment variable names are case sensitive.
- Even if a value contains spaces, you do not have to enclose the value in "" (double quotation marks).
- The environment variables configured with the environment variable configuration file are propagated only to the AWS CLI executed from an AWS Elastic IP resource, an AWS Virtual IP resource, an AWS DNS resource, an AWS Elastic IP monitor resource, an AWS Virtual IP monitor resource, an AWS DNS monitor resource, and an AWS AZ monitor resource. Therefore, the configured variables are not propagated to any other script (e.g. a script before final action, a script before and after activation/deactivation, and a script to be run from EXEC resources). To execute the AWS CLI with such a script, configure necessary environment variables with the corresponding script.

#### VPC ID (Within 45 bytes) [Server Individual Setup](#)

For VIP control, specify the VPC ID to which the server belongs. To specify an individual VPC ID for the servers, enter the VPC ID of any server on the Common tab and specify a VPC ID for the other servers individually.

For how to configure the routing, see the following:

"Configuring the VPC Environment" in the "EXPRESSCLUSTER X HA Cluster Configuration Guide for Amazon Web Services (Linux)"

#### ENI ID (Within 45 bytes) [Server Individual Setup](#)

For VIP control, specify the ENI ID of VIP routing destination. For the ENI ID to specify, Source/Dest. Check must be disabled beforehand. This must be set for each server. On the Common tab, enter the ENI ID of any server, and specify an ENI ID for the other servers individually.

### AWS Virtual IP Resource Tuning Properties

#### Parameter tab

The screenshot shows a dialog box titled "AWS Virtual Ip Resource Tuning Properties". It has a "Parameter" tab selected. Under the "AWS CLI" section, there is a "Timeout\*" label, a text input field containing "100", and a "sec" unit label. Below this is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

**Timeout** (1 to 999)

Set the timeout of the AWS CLI command to be executed for AWS Virtual IP resource activation/deactivation.

## 3.18 Understanding AWS DNS resources

### 3.18.1 Dependencies of AWS DNS resources

By default, this function does not depend on any group resource type.

### 3.18.2 What is an AWS DNS resource?

Fig. 3.137: Configuration with an AWS DNS resource

An AWS DNS resource registers an IP address corresponding to the virtual host name (DNS name) used in Amazon Web Services (hereinafter, referred to as "AWS") by executing AWS CLI at activation, and deletes it by executing AWS CLI at deactivation.

A client can access the node on which failover groups are active with the virtual host name.

By using AWS DNS resources, clients do not need to be aware of switching access destination node when a failover occurs or moving a group migration.

An AWS Elastic IP resource, an AWS Virtual IP resource, and an AWS DNS resource can be used together.

If using AWS DNS resources, you need to take the following preparations before establishing a cluster.

- Creating Hosted Zone of Amazon Route 53
- Installing AWS CLI

### 3.18.3 Notes on AWS DNS resources

- In client access using a virtual host name (DNS name), if a failover group to which the AWS DNS resource is added resource is failed over, reconnection may be required.
- See "Setting up AWS DNS resources" in "Notes when creating EXPRESSCLUSTER configuration data" in Notes and Restrictions" in the "Getting Started Guide".

### 3.18.4 Applying environment variables to AWS CLI run from the AWS DNS resource

Specify environment variables in the environment variable configuration file to apply environment variables to the AWS CLI run from the AWS Elastic IP resource, AWS Virtual IP resource, AWS Elastic IP monitor resource and AWS AZ monitor resource.

This feature is useful when using a proxy server in an AWS environment.

The environment variable configuration file is stored in the following location.

<EXPRESSCLUSTER Installation path>/cloud/aws/clpaws\_setting.conf

The format of the environment variable configuration file is as follows:

Environment variable name = Value

(Example)

```
[ENVIRONMENT]
HTTP_PROXY = http://10.0.0.1:3128
HTTPS_PROXY = http://10.0.0.1:3128
```

To specify multiple values for a parameter, enter them in comma-delimited format. The following shows an example of specifying more than one non-destination for the environment variable NO\_PROXY:

(Example)

```
NO_PROXY = 169.254.169.254,ec2.ap-northeast-1.amazonaws.com
```

The specifications of the environment variable configuration file are as follows:

- Write [ENVIRONMENT] on the first line. If this is not set, the environment variables will not be set.
- If the environment variable configuration file does not exist or you do not have read permission for the file, the variables are ignored. This does not cause an activation failure or a monitor error.

- If the same environment variables already exist in the file, the values are overwritten.
- More than one environment variable can be set. Set one environment variable on each line.
- The settings are valid regardless of whether there are spaces before and after "=" or not.
- The settings are invalid if there is a space or tab in front of the environment variable name or if there are tabs before and after "=".
- Environment variable names are case sensitive.
- Even if a value contains spaces, you do not have to enclose the value in "" (double quotation marks).
- The environment variables configured with the environment variable configuration file are propagated only to the AWS CLI executed from an AWS Elastic IP resource, an AWS Virtual IP resource, an AWS DNS resource, an AWS Elastic IP monitor resource, an AWS Virtual IP monitor resource, an AWS DNS monitor resource, and an AWS AZ monitor resource. Therefore, the configured variables are not propagated to any other script (e.g. a script before final action, a script before and after activation/deactivation, and a script to be run from EXEC resources). To execute the AWS CLI with such a script, configure necessary environment variables with the corresponding script.

#### Hosted Zone ID (within 255 bytes)

Specify a Hosted Zone ID of Amazon Route 53.

#### Resource Record Set Name (within 255 bytes)

Specify the name of DNS A record. Put a dot (.) at the end of the name. When an escape character is included in **Resource Record Set Name**, a monitor error occurs. Set **Resource Record Set Name** with no escape character. Specify the value of **Resource Record Set Name** in lowercase letters.

#### IP Address (within 39 bytes) Server Individual Setup

Specify the IP address corresponding to the virtual host name (DNS name) (IPv4). For using the IP address of each server, enter the IP address on the tab of each server. For configuring a setting for each server, enter the IP address of an arbitrary server on **Common** tab, and configure the individual settings for the other servers.

**TTL (0 to 2147483647)**

Specify the time to live (TTL) of the cache.

**Delete a record set at deactivation**

- When the check box is selected:  
The record set is delete when it is deactivated.
- When the check box is not selected (default):  
The record set is not deleted when it is deactivated. If it is not deleted, the remaining virtual host name (DNS name) may be accessed from a client.

**Tuning**

Opens the AWS DNS Resource Tuning Properties dialog box where you can make detailed settings for the AWS DNS resource.

**AWS DNS Resource Tuning Properties**

**Parameter tab**

The screenshot shows a dialog box titled "AWS DNS Resource Tuning Properties". It has a "Parameter" tab selected. Below the tab, there is a section titled "AWS CLI". Under this section, there is a "Timeout\*" label, a text input field containing the value "100", and a "sec" label. Below the input field, there is an "Initialize" button. At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

**Timeout (1 to 999)**

Make the setting of the timeout of AWS CLI command executed for the activation and/or deactivation of the AWS DNS resource.

## 3.19 Understanding Azure probe port resources

### 3.19.1 Dependencies of Azure probe port resources

By default, this function does not depend on any group resource type.

### 3.19.2 What is an Azure probe port resource?

Client applications can use the global IP address called a public virtual IP (VIP) address (referred to as a VIP in the remainder of this document) to access virtual machines on an availability set in the Microsoft Azure environment.

By using VIP, clients do not need to be aware of switching access destination server when a failover occurs or moving a group migration.

Fig. 3.138: Configuration with an Azure probe port resource

To access the cluster created on the Microsoft Azure environment in the figure above, specify the end point for communicating from the outside with VIP or the end point for communicating from the outside with the DNS name. The active and standby nodes of the cluster are switched by controlling the Microsoft Azure load balancer (Load Balancer in the figure above) from EXPRESSCLUSTER. For control, Health Check is used.

At activation, start the probe port control process for waiting for alive monitoring (access to the probe port) from the Azure load balancer.

At deactivation, stop the probe port control process for waiting for alive monitoring (access to the probe port).

Azure probe port resources also support the Internal Load Balancing of Microsoft Azure. For Internal Load Balancing, the VIP is the private IP address of Azure.

Fig. 3.139: Configuration with an Azure probe port resource (for Internal Load Balancing)

### 3.19.3 Notes on Azure probe port resources

- If the private port and the probe port are the same, you need not add Azure probe port resources or Azure probe port monitor resources.
- Refer to "Azure probe port resource settings" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

## 3.20 Understanding Azure DNS resources

### 3.20.1 Dependencies of Azure DNS resources

By default, this function does not depend on any group resource type.

### 3.20.2 What is an Azure DNS resource?

Fig. 3.140: Configuration with an Azure DNS resource

An Azure DNS resource controls an Azure DNS record set and DNS A record to obtain an IP address set from the virtual host name (DNS name).

A client can access the node on which failover groups are active with the virtual host name.

By using Azure DNS resources, clients do not need to be aware of switching access destination node on Azure DNS when a failover occurs or moving a group migration.

If using Azure DNS resources, you need to take the following preparations before establishing a cluster. For details, see "EXPRESSCLUSTER X HA Cluster Configuration Guide for Microsoft Azure (Linux)".

- Creating Microsoft Azure Resource Group and DNS zone
- Installing Azure CLI  
Use Azure CLI (Azure CLI 1.0) for Red Hat Enterprise Linux 6 and OS with compatibility.  
Use Azure CLI (Azure CLI 2.0) for Red Hat Enterprise Linux 7 and OS with compatibility.
- Installing Python (only when Azure CLI 2.0 is used)

### **3.20.3 Notes on Azure DNS resources**

- In client access using a virtual host name (DNS name), if a failover group to which the Azure DNS resource is added is failed over, reconnection may be required.
- See "Setting up Azure DNS resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".
- See "Azure DNS resources" in " Before installing EXPRESSCLUSTER" in "Notes and Restrictions" in the "Getting Started Guide".

**Delete a record set at deactivation** ☒

[Tuning](#)

[OK](#) [Cancel](#) [Apply](#)

**Record Set Name** (within 253 bytes)

Specify the name of the record set in which Azure DNS A record is registered.

**Zone Name** (within 253 bytes)

Specify the name of the DNS zone to which the record set of Azure DNS belongs.

**IP Address** (within 39 bytes) *Server Individual Setup*

Specify the IP address corresponding to the virtual host name (DNS name) (IPv4). For using the IP address of each server, enter the IP address on the tab of each server. For configuring a setting for each server, enter the IP address of an arbitrary server on Common tab, and configure the individual settings for the other servers.

**TTL** (0 to 2147483647)

Specify the time to live (TTL) of the cache.

**Resource Group Name** (within 180 bytes)

Specify the name of Microsoft Azure Resource Group to which the DNS zone belongs.

**User URI** (within 2083 bytes)

Specify the user URI to log on to Microsoft Azure.

**Tenant ID** (within 36 bytes)

Specify the tenant ID to log on to Microsoft Azure.

**File Path of Service Principal** (within 1023 bytes)

Specify the file name of the service principal to log in to Microsoft Azure (file name of the credential). Specify with an absolute path.

**Thumbprint of Service Principal** (within 256 bytes)

Specify the service principal to log in to Microsoft Azure (Thumbprint on Certificate). Enter only when using Azure CLI 1.0.

**Azure CLI File Path** (within 1023 bytes)

Specify the installation path of Azure CLI and the file name. Specify with an absolute path.

**Delete a record set at deactivation**

- When the check box is selected (default):  
The record set is deleted when it is deactivated.
- When the check box is not selected:  
The record set is not deleted when it is deactivated. If it is not deleted, the remaining virtual host name (DNS name) may be accessed from a client.

**Tuning**

Opens the **AWS DNS Resource Tuning Properties** dialog box where you can make detailed settings for the Azure DNS resource.

**Server separate setting**

Opens the **Server Separate Setting** dialog box. An IP address different depending on servers is set.

**Azure DNS Resource Tuning Properties**

**Parameter tab**

The screenshot shows a dialog box titled "Azure DNS Resource Tuning Properties". It has a "Parameter" tab selected. Below the tab, there is a section labeled "Azure CLI". Under this section, there is a "Timeout\*" label, a text input field containing the value "100", and a "sec" label. At the bottom left of the dialog, there is an "Initialize" button. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

**Timeout (1 to 999)**

Make the setting of the timeout of the Azure CLI command executed for the activation and/or deactivation of the Azure DNS resource.

## 3.21 Understanding Google Cloud Virtual IP resources

### 3.21.1 Dependencies of Google Cloud Virtual IP resources

By default, this function does not depend on any group resource type.

### 3.21.2 What is an Google Cloud Virtual IP resource?

For virtual machines in the Google Cloud Platform environment, client applications can use a virtual IP (VIP) address to connect to the node that constitutes a cluster. Using the VIP address eliminates the need for clients to be aware of switching between the virtual machines even after a failover or a group migration occurs.

Fig. 3.141: Configuration with a Google Cloud Virtual IP resource

To access the cluster created in the Google Cloud Platform environment as in the figure above, specify the port for communicating from the outside as well as the VIP address or DNS name. The active and standby nodes of the cluster are switched by controlling the load balancer of Google Cloud Platform (Cloud Load Balancing in the figure above) from EXPRESSCLUSTER. For this control, Health Check (in the figure above) is used.

At activation, start the control process for awaiting a health check from the load balancer of Google Cloud Platform, and open the port specified in **Port Number**.

At deactivation, stop the control process for awaiting the health check, and close the port specified in **Port Number**.

Google Cloud virtual IP resources support the internal load balancing of Google Cloud Platform.

### 3.21.3 Notes on Google Cloud Virtual IP resources

- According to the Google Cloud Platform specification, External TCP Network Load Balancer requires legacy health checks using the HTTP protocol.

Google Cloud Virtual IP resources only support health checks that use the TCP protocol and cannot respond to health checks from External TCP Network Load Balancer.

Therefore, HA cluster using Google Cloud Virtual IP resources by External TCP Network Load Balancer cannot be used. Use an Internal TCP Load Balancer.

Refer to the following.

Health checks overview:

<https://cloud.google.com/load-balancing/docs/health-check-concepts/>

- If the private port is the same as the health-check port, you need not add Google Cloud virtual IP resources or Google Cloud virtual IP monitor resources.
- Refer to "Getting Started Guide" -> "Notes and Restrictions" -> "Notes when creating EXPRESSCLUSTER configuration data" -> "Setting up Google Cloud Virtual IP resources".

### 3.21.4 Details tab

The screenshot shows a dialog box titled "Resource Properties | gcvip1". It has four tabs: "Info", "Dependency", "Recovery Operation", and "Details". The "Details" tab is selected. Inside the tab, there is a "Port Number" label with a red asterisk, followed by a text input field containing the value "12345". Below the input field is a button labeled "Tuning". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Port Number (1 to 65535)

Specify a port number to be used by the load balancer of Google Cloud Platform for the health check of each node: the value specified as the port number in configuring the load balancer for health checks. For the load balancer, specify **TCP load balancing**.

#### Tuning

Displays the **Google Cloud Virtual IP Resource Tuning Properties** dialog box, where you can make advanced settings for the Google Cloud virtual IP resource.

#### Google Cloud Virtual IP Resource Tuning Properties

Google Cloud Virtual IP Resource Tuning Properties

Health check timeout\* 30 sec

Initialize

OK Cancel Apply

**Health check timeout** (5 to 999999999)

Specify a timeout value for awaiting a health check from the load balancer of Google Cloud Platform, in order to check whether the load balancer periodically performs health checks.

## 3.22 Understanding Google Cloud DNS resources

### 3.22.1 Dependencies of Google Cloud DNS resources

By default, this function does not depend on any group resource type.

### 3.22.2 What is an Google Cloud DNS resource?

A Google Cloud DNS resource controls a Google Cloud DNS record set and DNS A record to obtain an IP address set from the virtual host name (DNS name).

A client can access the node on which failover groups are active with the virtual host name.

By using Google Cloud DNS resources, clients do not need to be aware of switching access destination node on Google Cloud DNS when a failover occurs or moving a group migration.

### 3.22.3 Notes on Google Cloud DNS resources

- See "Setting up Google Cloud DNS resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".
- See "Google Cloud DNS resources" in "Before installing EXPRESSCLUSTER" in "Notes and Restrictions" in the "Getting Started Guide".

Specify the time to live (TTL) of the cache.

**Delete a record set at deactivation**

- When the check box is selected (default):  
The record set is deleted when it is deactivated.
- When the check box is not selected:  
The record set is not deleted when it is deactivated. If it is not deleted, the remaining virtual host name (DNS name) may be accessed from a client.

## 3.23 Understanding Oracle Cloud Virtual IP resources

### 3.23.1 Dependencies of Oracle Cloud Virtual IP resources

By default, this function does not depend on any group resource type.

### 3.23.2 What is an Oracle Cloud Virtual IP resource?

For virtual machines in the Oracle Cloud Infrastructure environment, client applications can use a public virtual IP (VIP) address to connect to the node that constitutes a cluster. Using the VIP address eliminates the need for clients to be aware of switching between the virtual machines even after a failover or a group migration occurs.

Fig. 3.142: Configuration with an Oracle Cloud Virtual IP resource

To access the cluster created in the Oracle Cloud Infrastructure environment as in the figure above, specify the port for communicating from the outside as well as the VIP (global IP) address or DNS name. The active and standby nodes

of the cluster are switched by controlling the load balancer of Oracle Cloud Infrastructure (Load Balancer in the figure above) from EXPRESSCLUSTER. For this control, Health Check (in the figure above) is used.

At activation, start the control process for awaiting a health check from the load balancer of Oracle Cloud Infrastructure, and open the port specified in **Port Number**.

At deactivation, stop the control process for awaiting the health check, and close the port specified in **Port Number**.

Oracle Cloud virtual IP resources also support private load balancers of Oracle Cloud Infrastructure. For a private load balancer, the VIP address is the private IP address of Oracle Cloud Infrastructure.

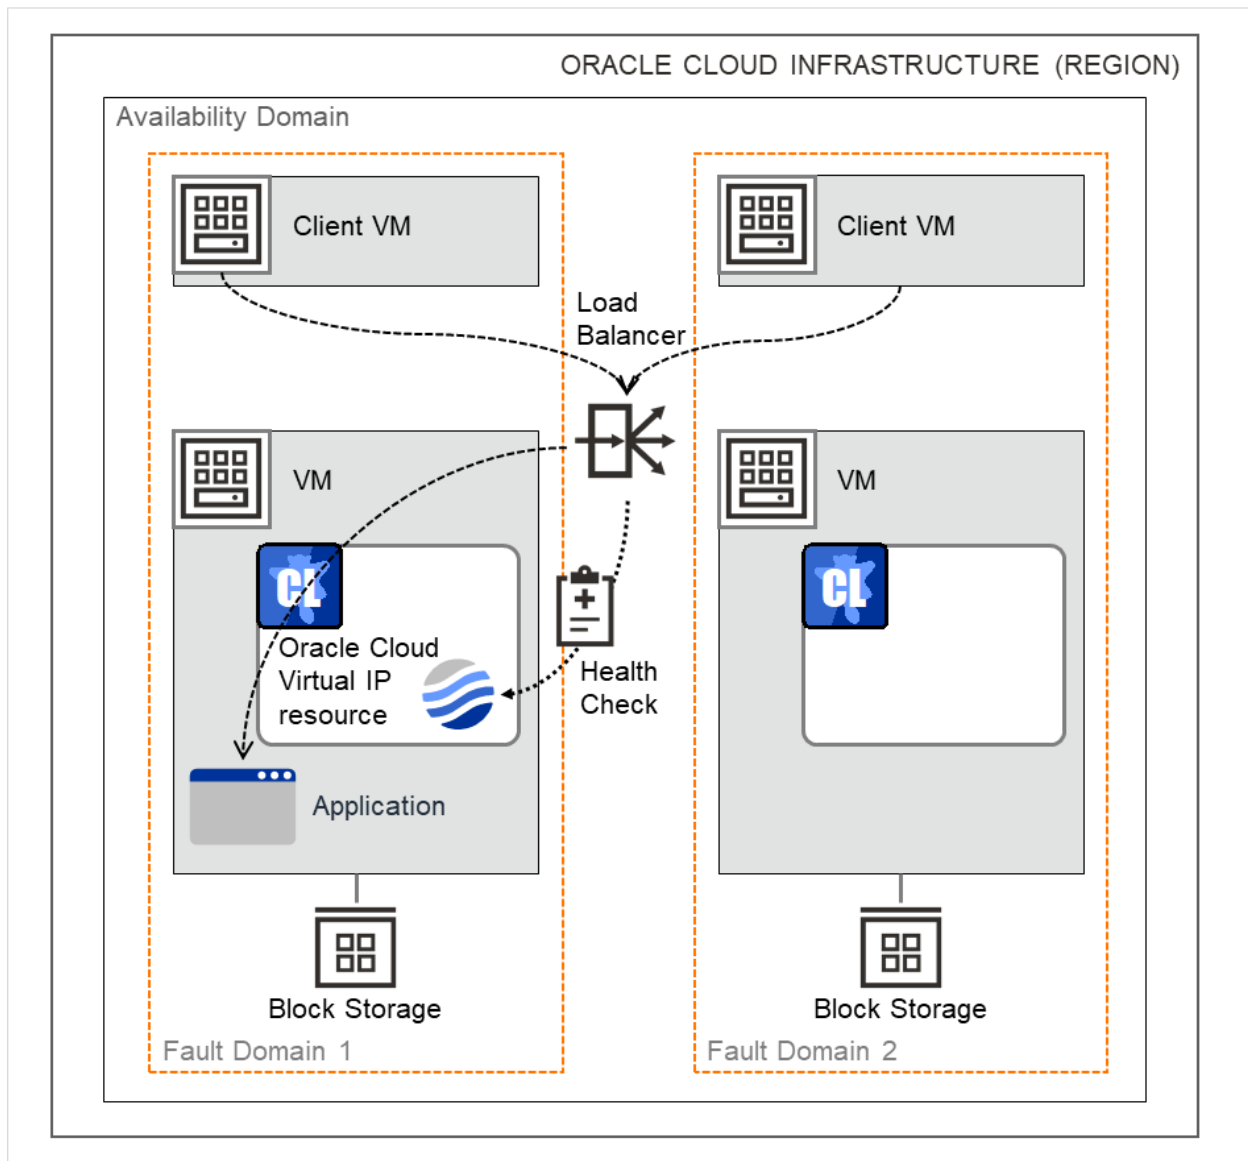

Fig. 3.143: Configuration with an Oracle Cloud Virtual IP resource (for a private load balancer)

### 3.23.3 Notes on Oracle Cloud Virtual IP resources

- If the private port is the same as the health-check port, you need not add Oracle Cloud virtual IP resources or Oracle Cloud virtual IP monitor resources.
- Refer to "Getting Started Guide" -> "Notes and Restrictions" -> "Notes when creating EXPRESSCLUSTER configuration data" -> "Setting up Oracle Cloud Virtual IP resources".

### 3.23.4 Details tab

The screenshot shows a dialog box titled "Resource Properties | ocvip1" with a close button (X) in the top right corner. Below the title bar, there are four tabs: "Info", "Dependency", "Recovery Operation", and "Details", with "Details" being the active tab. The main content area contains a label "Port Number\*" followed by a text input field containing the value "12345". Below this, there is a button labeled "Tuning". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Port Number (1 to 65535)

Specify a port number to be used by the load balancer of Oracle Cloud Infrastructure for the health check of each node: the value specified as the port number in configuring the backend set for health checks. For the health check protocol, specify TCP.

#### Tuning

Displays the **Oracle Cloud Virtual IP Resource Tuning Properties** dialog box, where you can make advanced settings for the Oracle Cloud virtual IP resource.

#### Oracle Cloud Virtual IP Resource Tuning Properties

The screenshot shows a dialog box titled "Oracle Cloud Virtual IP Resource Tuning Properties". The main content area contains a label "Health check timeout\*" followed by a text input field containing the value "30" and the unit "sec". Below this, there is a button labeled "Initialize". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Health check timeout (5 to 999999999)

Specify a timeout value for awaiting a health check from the load balancer of Oracle Cloud Infrastructure, in order to check whether the load balancer periodically performs health checks.

## MONITOR RESOURCE DETAILS

This chapter provides detailed information on monitor resources. Monitor resource is a unit to perform monitoring.

This chapter covers:

- 4.1. *Monitor resource*
- 4.2. *Monitor Common Properties*
- 4.3. *Monitor resource properties*
- 4.4. *Understanding the disk monitor resources*
- 4.5. *Understanding IP monitor resources*
- 4.6. *Understanding floating IP monitor resources*
- 4.7. *Understanding NIC Link Up/Down monitor resources*
- 4.8. *Understanding mirror disk connect monitor resources*
- 4.9. *Understanding mirror disk monitor resources*
- 4.10. *Understanding hybrid disk connect monitor resources*
- 4.11. *Understanding hybrid disk monitor resources*
- 4.12. *Understanding PID monitor resources*
- 4.13. *Understanding User mode monitor resources*
- 4.14. *Understanding multi target monitor resources*
- 4.15. *Understanding virtual IP monitor resources*
- 4.16. *Understanding ARP monitor resources*
- 4.17. *Understanding custom monitor resources*
- 4.18. *Understanding volume manager monitor resources*
- 4.19. *Understanding message receive monitor resources*
- 4.20. *Understanding VM monitor resources*
- 4.21. *Understanding Dynamic DNS monitor resources*
- 4.22. *Understanding process name monitor resources*
- 4.23. *Understanding BMC monitor resources*
- 4.24. *Understanding DB2 monitor resources*
- 4.25. *Understanding FTP monitor resources*

- 4.26. *Understanding HTTP monitor resources*
- 4.27. *Understanding IMAP4 monitor resources*
- 4.28. *Understanding MySQL monitor resources*
- 4.29. *Understanding NFS monitor resources*
- 4.30. *Understanding ODBC monitor resources*
- 4.31. *Understanding Oracle monitor resources*
- 4.32. *Understanding Oracle Clusterware Synchronization Management monitor resources*
- 4.33. *Understanding POP3 monitor resources*
- 4.34. *Understanding PostgreSQL monitor resources*
- 4.35. *Understanding Samba monitor resources*
- 4.36. *Understanding SMTP monitor resources*
- 4.37. *Understanding SQL Server monitor resources*
- 4.38. *Understanding Sybase monitor resources*
- 4.39. *Understanding Tuxedo monitor resources*
- 4.40. *Understanding WebLogic monitor resources*
- 4.41. *Understanding WebSphere monitor resources*
- 4.42. *Understanding WebOTX monitor resources*
- 4.43. *Understanding JVM monitor resources*
- 4.44. *Understanding System monitor resources*
- 4.45. *Understanding Process resource monitor resources*
- 4.46. *Understanding AWS Elastic IP monitor resources*
- 4.47. *Understanding AWS Virtual IP monitor resources*
- 4.48. *Understanding AWS AZ monitor resources*
- 4.49. *Understanding AWS DNS monitor resources*
- 4.50. *Understanding Azure probe port monitor resources*
- 4.51. *Understanding Azure load balance monitor resources*
- 4.52. *Understanding Azure DNS monitor resources*
- 4.53. *Understanding Google Cloud Virtual IP monitor resources*
- 4.54. *Understanding Google Cloud load balance monitor resources*
- 4.55. *Understanding Google Cloud DNS monitor resources*
- 4.56. *Understanding Oracle Cloud Virtual IP monitor resources*
- 4.57. *Understanding Oracle Cloud load balance monitor resources*

## 4.1 Monitor resource

A monitor resource refers to a resource that monitors a specified target to be monitored. When detecting an error in a target to be monitored, a monitor resource restarts a group resource and/or executes failover.

Currently supported monitor resources:

Monitor resource name	Abbreviation	Functional overview	Supported version
Disk Monitor Resource	diskw	See " <i>Understanding the disk monitor resources</i> ".	4.0.0-1 or later
IP Monitor Resource	ipw	See " <i>Understanding IP monitor resources</i> ".	4.0.0-1 or later
Floating IP Monitor Resource	fipw	See " <i>Understanding floating IP monitor resources</i> ".	4.0.0-1 or later
NIC Link Up/Down Monitor Resource	miiw	See " <i>Understanding NIC Link Up/Down monitor resources</i> ".	4.0.0-1 or later
Mirror Disk Connect Monitor Resource	mdnw	See " <i>Understanding mirror disk connect monitor resources</i> ".	4.0.0-1 or later
Mirror Disk Monitor Resource	mdw	See " <i>Understanding mirror disk monitor resources</i> ".	4.0.0-1 or later
Hybrid Disk Connect Monitor Resource	hdnw	See " <i>Understanding hybrid disk connect monitor resources</i> ".	4.0.0-1 or later
Hybrid Disk Monitor Resource	hdw	See " <i>Understanding hybrid disk monitor resources</i> ".	4.0.0-1 or later
PID Monitor Resource	pidw	See " <i>Understanding PID monitor resources</i> ".	4.0.0-1 or later
User-Mode Monitor Resource	userw	See " <i>Understanding User mode monitor resources</i> ".	4.0.0-1 or later
Multi Target Monitor Resource	mtw	See " <i>Understanding multi target monitor resources</i> ".	4.0.0-1 or later
Virtual IP Monitor Resource	vipw	See " <i>Understanding virtual IP monitor resources</i> ".	4.0.0-1 or later
ARP Monitor Resource	arpw	See " <i>Understanding ARP monitor resources</i> ".	4.0.0-1 or later
Custom Monitor Resource	genw	See " <i>Understanding custom monitor resources</i> ".	4.0.0-1 or later
Volume Manager Monitor Resource	volmgrw	See " <i>Understanding volume manager monitor resources</i> ".	4.0.0-1 or later
Message Receive Monitor Resource	mrw	See " <i>Understanding message receive monitor resources</i> ".	4.0.0-1 or later
VM Monitor Resource	vmw	See " <i>Understanding VM monitor resources</i> ".	4.0.0-1 or later
Dynamic DNS Monitor Resource	ddns	See " <i>Understanding Dynamic DNS monitor resources</i> ".	4.0.0-1 or later
Process Name Monitor Resource	psw	See " <i>Understanding process name monitor resources</i> ".	4.0.0-1 or later
BMC Monitor Resource	bmcw	See " <i>Understanding BMC monitor resources</i> ".	4.0.0-1 or later
DB2 Monitor Resource <sup>1</sup>	db2w	See " <i>Understanding DB2 monitor resources</i> ".	4.0.0-1 or later
FTP Monitor Resource <sup>1</sup>	ftpw	See " <i>Understanding FTP monitor resources</i> ".	4.0.0-1 or later

### 4.1.1 Status of monitor resources after monitoring starts

The status of some monitor resources might be "Caution" if there is a period of time following the start of monitoring in which monitoring of that resource is not yet ready.

Caution status is possible for the following monitor resources.

- Dynamic DNS Monitor Resource
- Message Receive Monitor Resource
- Custom Monitor Resource (whose monitor type is **Asynchronous**)
- Virtual IP Monitor Resource
- DB2 Monitor Resource
- BMC Monitor Resource
- System Monitor Resource
- Process Resource Monitor Resource
- JVM Monitor Resource
- MySQL Monitor Resource
- ODBC Monitor Resource
- Oracle Monitor Resource
- Oracle Clusterware Synchronization Management Monitor Resource
- PostgreSQL Monitor Resource
- Process Name Monitor Resource
- SQL Server Monitor Resource
- Sybase Monitor Resource

<sup>1</sup> To use this monitor resource, you need to register a license. For details on how to register a license, see the "Installation and Configuration Guide".

## 4.1.2 Monitor timing of monitor resource

There are two types of monitoring by monitor resources; **Always** and **Active**.

The monitoring timing differs depending on monitor resources:

a) Always:

Monitoring is performed by the monitor resource all the time.

b) Active:

Monitoring is performed by the monitor resource while a specified group resource is active. The monitor resource does not monitor while the group resource is not activated.

- (1) Cluster startup
- (2) Group activation
- (3) Group deactivation
- (4) Cluster stop

Fig. 4.1: Two types of monitoring by monitor resources: **Always** and **Active**

Monitor resource	Monitor timing	Target resource
Disk Monitor Resource	Always or when activated	All
IP Monitor Resource	Always or when activated	All
User-Mode Monitor Resource	Always (Fixed)	-
Mirror Disk Monitor Resource	Always (Fixed)	-
Mirror Disk Connect Monitor Resource	Always (Fixed)	-
Hybrid Disk Monitor Resource	Always (Fixed)	-
Hybrid Disk Connect Monitor Resource	Always (Fixed)	-
NIC Link Up/Down Monitor resource	Always or when activated	All
PID Monitor resource	Fixed to while activating	exec
Multi Target Monitor Resource	Always or when activated	All
Virtual IP Monitor Resource	When activated (Fixed)	vip
ARP Monitor Resource	When activated (Fixed)	fip, vip
Custom Monitor resource	Always or when activated	All
VM Monitor Resource	Always (Fixed)	vm
Message Receive Monitor Resource	Always or when activated	mrw
Volume Manager Monitor Resource	Always or when activated	volmgr

Continued on next page

Table 4.2 – continued from previous page

Monitor resource	Monitor timing	Target resource
Dynamic DNS Monitor Resource	Always (Fixed)	ddns
Process Name Monitor Resource	Always or when activated	All
BMC Monitor Resource	Always (Fixed)	-
DB2 Monitor Resource	When activated (Fixed)	exec
FTP Monitor Resource	Always or when activated	exec
HTTP Monitor Resource	Always or when activated	exec
IMAP4 Monitor Resource	Always or when activated	exec
MySQL Monitor Resource	When activated (Fixed)	exec
NFS Monitor Resource	Always or when activated	exec
ODBC Monitor Resource	When activated (Fixed)	exec
Oracle Monitor Resource	When activated (Fixed)	exec
Oracle Clusterware Synchronization Management Monitor Resource	Always (Fixed)	-
POP3 Monitor Resource	When activated (Fixed)	exec
PostgreSQL Monitor Resource	When activated (Fixed)	exec
Samba Monitor Resource	Always or when activated	exec
SMTP Monitor Resource	Always or when activated	exec
SQL Server Monitor Resource	When activated (Fixed)	exec
Sybase Monitor Resource	When activated (Fixed)	exec
Tuxedo Monitor Resource	Always or when activated	exec
WebLogic Monitor Resource	Always or when activated	exec

Google Cloud load balance monitor resource	Always (Fixed)	gcvip
Google Cloud DNS monitor resource	When activated (Fixed)	gcdns
Oracle Cloud Virtual IP monitor resource	When activated (Fixed)	ocvip
Oracle Cloud load balance monitor resource	Always (Fixed)	ocvip

### 4.1.3 Suspending and resuming monitoring on monitor resources

Monitor resource can temporarily suspend monitoring and resume it.

Monitoring can be suspended and resumed by the following two methods:

- Operation on the Cluster WebUI
- Operation by the clpmonctrl command  
The clpmonctrl command can control monitor resources on a server where the command is run or on a specified server.

Some monitor resources can suspend and resume monitoring and others cannot. For details, see the list below.

<b>Monitor Resource</b>	<b>Control</b>
Disk Monitor Resource	Possible
IP Monitor Resource	Possible
User-mode Monitor Resource	Possible
Mirror Disk Monitor Resource	Possible
Mirror Disk Connect Monitor Resource	Possible
Hybrid Disk Monitor Resource	Possible
Hybrid Disk Connect Monitor Resource	Possible
NIC Link Up/Down Monitor Resource	Possible
PID Monitor Resource	Possible
Multi Target Monitor Resource	Possible
Virtual IP Monitor Resource	Impossible
ARP Monitor Resource	Impossible
Custom Monitor Resource	Possible
VM Monitor Resource	Possible
Message Receive Monitor Resource	Possible
Volume Manager Monitor Resource	Possible
Dynamic DNS Monitor Resource	Impossible
Process Name Monitor Resource	Possible
BMC Monitor Resource	Possible
DB2 Monitor Resource	Possible
FTP Monitor Resource	Possible
HTTP Monitor Resource	Possible
IMAP4 Monitor Resource	Possible
MySQL Monitor Resource	Possible
NFS Monitor Resource	Possible
ODBC Monitor Resource	Possible
Oracle Monitor Resource	Possible
Oracle Clusterware Synchronization Management Monitor Resource	Possible
POP3 Monitor Resource	Possible
PostgreSQL Monitor Resource	Possible
Samba Monitor Resource	Possible
SMTP Monitor Resource	Possible
SQL Server Monitor Resource	Possible
Sybase Monitor Resource	Possible
Tuxedo Monitor Resource	Possible
WebSphere Monitor Resource	Possible
WebLogic Monitor Resource	Possible

Continued on next page

Table 4.3 – continued from previous page

Monitor Resource	Control
WebOTX Monitor Resource	Possible
JVM Monitor Resource	Possible
System Monitor Resource	Possible
Process Resource Monitor Resource	Possible
Floating IP Monitor Resource	Possible
AWS Elastic IP Monitor resource	Possible
AWS Virtual IP Monitor resource	Possible
AWS AZ Monitor resource	Possible
AWS DNS Monitor resource	Possible
Azure probe port monitor resource	Possible
Azure load balance monitor resource	Possible
Azure DNS Monitor resource	Possible
Google Cloud Virtual IP monitor resource	Possible
Google Cloud load balance monitor resource	Possible
Google Cloud DNS monitor resource	Possible
Oracle Cloud Virtual IP monitor resource	Possible
Oracle Cloud load balance monitor resource	Possible

On the Cluster WebUI, shortcut menus of the monitor resources which cannot control monitoring are disabled. The `clpmonctrl` command only controls the resources which can control monitoring. For monitor resources which cannot control monitoring, a warning message is displayed and controls are not performed.

Suspending monitoring on a monitor resource is disabled if one of the following operations is performed.

- Resume operation on Cluster WebUI
- Resume operation by using the `clpmonctrl` command
- Stop the cluster
- Suspend the cluster

#### 4.1.4 Enabling and disabling dummy failure of monitor resources

You can enable and disable dummy failure of monitor resources. Use one of the following methods to enable or disable dummy failure.

- Operation on Cluster WebUI (verification mode)  
On the Cluster WebUI (verification mode), shortcut menus of the monitor resources which cannot control monitoring are disabled.
- Operation by using the `clpmonctrl` command  
The `clpmonctrl` command can control the server where this command is run or the monitor resources of the specified server. When the `clpmonctrl` command is executed on monitor resource which cannot be controlled, dummy failure is not enabled even though the command succeeds.

Some monitor resources can enable and disable dummy failure and others cannot.

For details, see "*Controlling monitor resources (clpmonctrl command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

Dummy failure of a monitor resource is disabled if the following operations are performed.

- Dummy failure was disabled on Cluster WebUI (verification mode)
- "Yes" was selected from the dialog box displayed when the Cluster WebUI mode changes from verification mode to a different mode.
- -n was specified to enable dummy failure by using the clpmonctrl command
- Stop the cluster
- Suspend the cluster

### 4.1.5 Monitoring interval for monitor resource

All monitor resources except the user-mode monitor resource monitors their targets at every monitor interval.

The following illustrates the timeline of how a monitor resource monitors its target and finds error/no error with the configuration below:

#### When no error is detected

The following figure illustrates monitoring started/resumed after the cluster is started. When the main monitoring process receives the monitoring result, the monitoring is repeatedly started at the monitor intervals.

Examples of behavior when the following values are set.

<Monitor>

Monitor Interval 30 sec

Monitor Timeout 60 sec

Monitor Retry Count 0 times

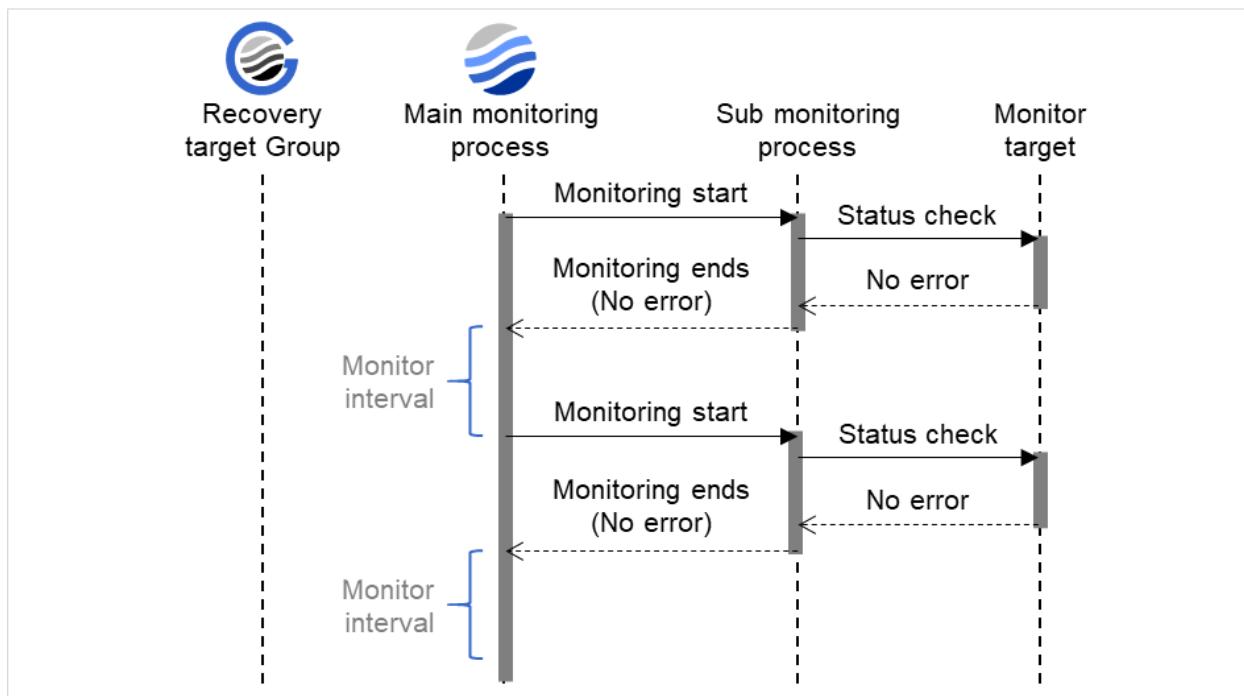

Fig. 4.2: Monitor interval (when no error is detected)

**When an error is detected (without monitor retry setting)**

The following figure illustrates an error occurring in the monitor target, and the operation after the error is detected. When the main monitoring process receives the monitoring result (error), a failover of the group to be recovered (Recovery target Group) is performed.

When an error occurs, it is detected at the next monitoring and the recovery operation for the recovery target starts.

Examples of behavior when the following values are set.

<Monitor>

Monitor Interval 30 sec

Monitor Timeout 60 sec

Monitor Retry count 0 times

<Error detection>

Recovery Target group

Recovery Script Execution Count 0 times

Maximum Reactivation Count 0 times

Maximum Failover Count 1 time

Final Action None

Fig. 4.3: Monitor interval (when an error is detected without monitor retry setting)

**When an error is detected (with monitor retry settings)**

The following figure illustrates an error occurring in the monitor target, and the operation after the error is detected. When the main monitoring process receives the monitoring result (error), the monitoring continues by its specified

count of retries. If the monitoring target is still not recovered, a failover of the group to be recovered is performed.

When an error occurs, it is detected at the next monitoring. If recovery cannot be achieved within the monitor retries, the failover is started for the recovery target.

Examples of behavior when the following values are set.

<Monitor>

Monitor Interval 30 sec

Monitor Timeout 60 sec

Monitor Retry Count 2 times

<Error detection>

Recovery Target group

Recovery Script Execution Count 0 times

Maximum Reactivation Count 0 times

Maximum Failover Count 1 time

Final Action None

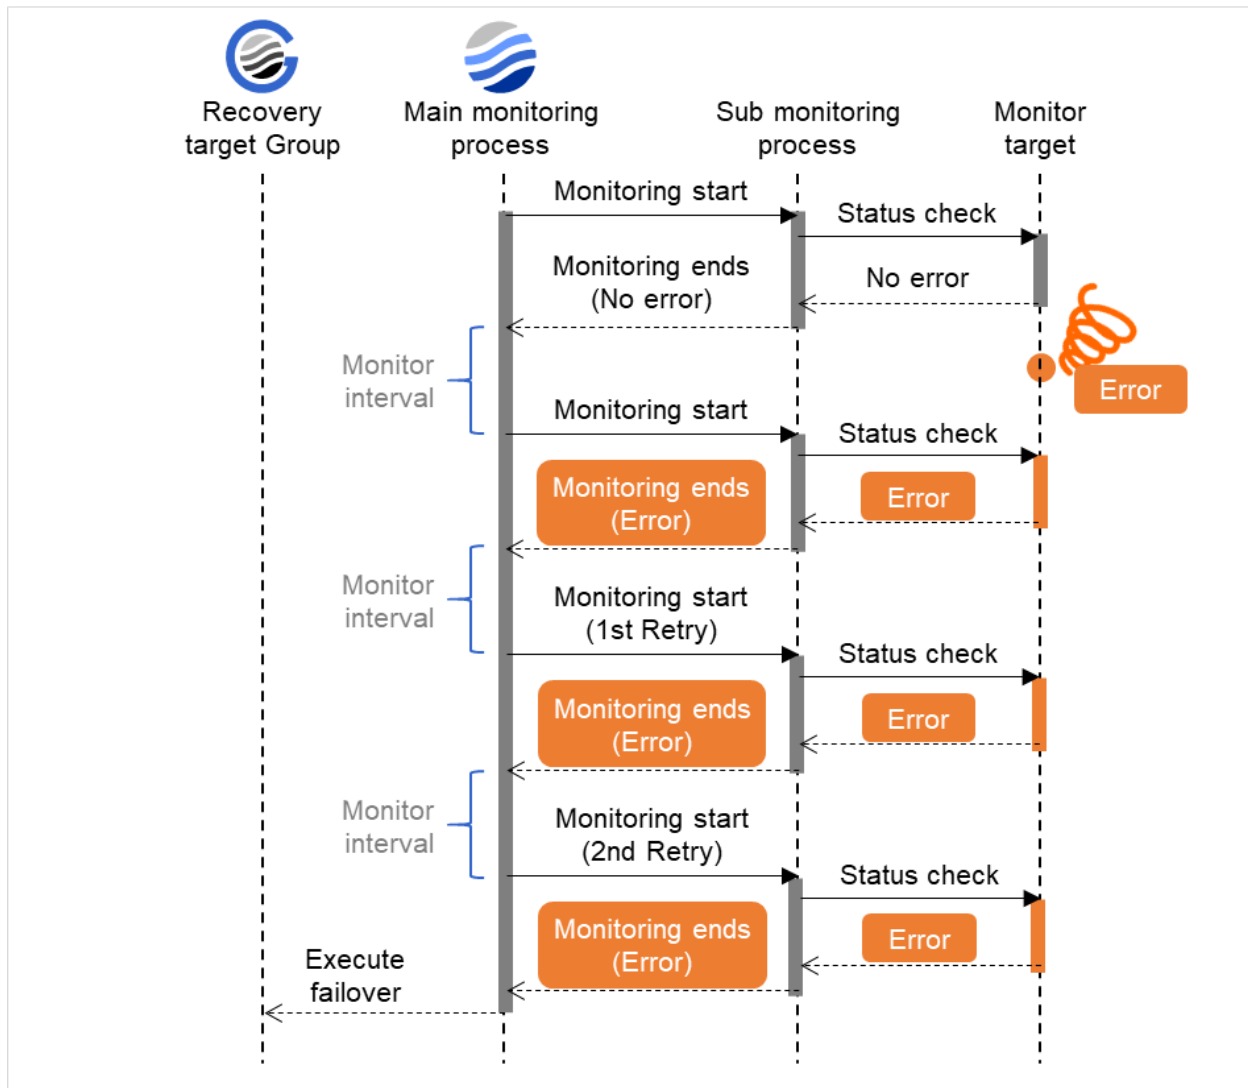

Fig. 4.4: Monitor interval (when an error is detected with monitor retry setting)

**When an error is detected (without monitor retry settings)**

The following figure illustrates operation in response to a monitoring process unfinished within a specified time. The main monitoring process starts the monitoring. Then, if the monitoring result cannot be obtained within a specified monitoring timeout time, a failover of the group to be recovered is performed.

Immediately after an occurrence of a monitoring timeout, the failover for the recovery target starts.

Examples of behavior when the following values are set.

<Monitor>

Monitor Interval 30 sec

Monitor Timeout 60 sec

Monitor Retry Count 0 times

<Error detection>

Recovery Target group

Recovery Script Execution Count 0 times

Maximum Reactivation Count 0 times

Maximum Failover Count 1 time

Final Action none

Fig. 4.5: Monitor interval (when a monitoring timeout is detected without monitor retry setting)

#### When a monitoring timeout is detected (with monitor retry setting)

The following figure illustrates operation in response to a monitoring process unfinished within a specified time. The main monitoring process starts the monitoring. Then, if the monitoring result cannot be obtained within a specified monitoring timeout time, the monitoring continues by its specified count of retries. If the monitoring result still cannot be obtained, a failover of the group to be recovered is performed.

When a monitoring timeout occurs, monitor retry is performed and failover is started for the recovery target.

Examples of behavior when the following values are set.

<Monitor>

Monitor Interval 30 sec

Monitor Timeout 60 sec

Monitor Retry Count 1 time

<Error detection>

Recovery Target group

Recovery Script Execution Count 0 times  
Maximum Reactivation Count 0 times  
Maximum Failover Count 1 time  
Final Action none

Fig. 4.6: Monitor interval (when a monitoring timeout is detected with monitor retry setting)

#### 4.1.6 Action when an error is detected by monitor resource

When an error is detected, the following recovery actions are taken against the recovery target in sequence:

- Execution of recovery script: this takes place when an error is detected in a monitor target.
- Reactivation of the recovery target: this takes place if the recovery script is executed up to the recovery script execution count. When the execution of a pre-reactivation script is specified, reactivation starts after that script has been executed.
- Failover: this takes place when reactivation fails for the number of times set in the reactivation threshold. When the execution of a pre-failover script is specified, failover starts after that script has been executed.

- Final action: this takes place when the error is detected even after the failover is executed for the number of times set in the failover threshold. When the execution of a pre-final-action script is specified, the final action starts after that script has been executed.

No recovery action is taken if the status of the recovery target is:

Recovery target	Status	Reactivation <sup>2</sup>	Failover <sup>3</sup>	Final action <sup>4</sup>
Group resource/ Failover group	Already stopped	No	No	No
	Being acti- vated/stopped	No	No	No
	Already activated	Yes	Yes	Yes
	Error	Yes	Yes	Yes
Local Server	-	-	-	Yes

Yes: Recovery action is taken No: Recovery action is not taken

---

**Note:** Do not work on the following operations by running commands or using the Cluster WebUI when a group resource (e.g. disk resource, EXEC resource) is set as a recovery target in the settings of error detection for the monitor resource, and recovery is in progress (reactivation -> failover -> final action) after detection of an error:

- Stop/suspend the cluster
- Start/stop/move a group

If you perform the above-mentioned operations while recovery caused by detection of an error by a monitor resource is in progress, other group resources of the group with an error may not stop.

However, the above-mentioned operations can be performed when the final action is completed.

When the status of the monitor resource recovers from an error (becomes normal), the reactivation count, failover count, and whether the final action is executed are all reset.

An unsuccessful recovery action is also counted into reactivation count or failover count.

---

The following is an example of the progress when only one server detects an error while the gateway is specified as an IP resource of the IP monitor resource:

Examples of behavior when the following values are set.

<Monitor>

Interval 30 sec

Timeout 30 sec

Retry Count 3 times

<Error detection>

---

<sup>2</sup> Effective only when the value for the reactivation threshold is set to 1 (one) or greater.

<sup>3</sup> Effective only when the value for the failover threshold is set to 1 (one) or greater.

<sup>4</sup> Effective only when an option other than No Operation is selected.

Recovery Target Failover Group A  
Recovery Script Execution Count 3 times  
Maximum Reactivation Count 3 times  
Maximum Failover Count 1 time  
Final Action No Operation

- (1) The following figure shows an example of monitoring by the IP monitor resource on two servers.  
To check for the aliveness, IP monitor resource 1 accesses the gateway's IP address at the intervals.

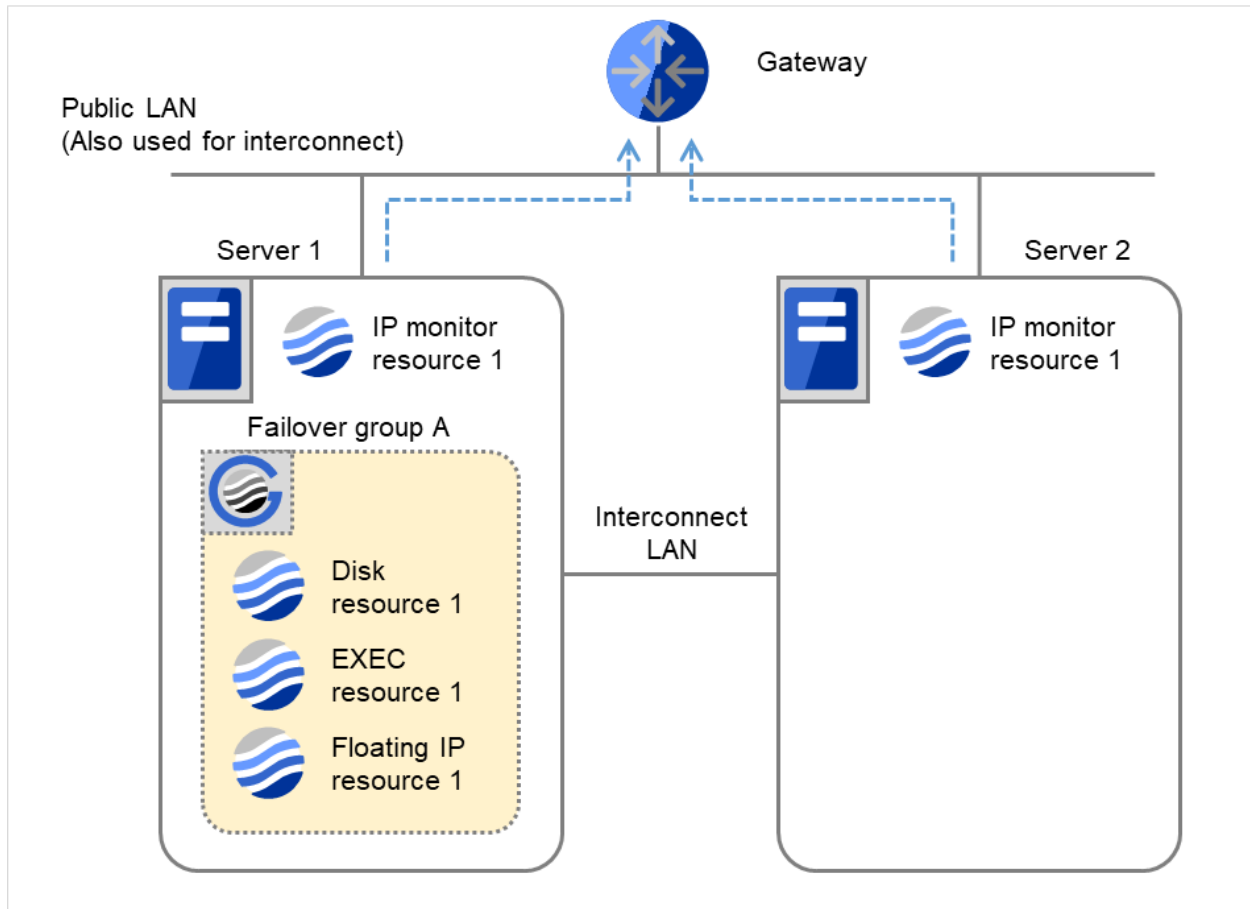

Fig. 4.7: Flow of error detection by the IP monitor resource: when only one server detects an error (1)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	0	0
Reactivation Count	0	0
Failover Count	0	0

- (2) IP monitor resource 1 detects an error (such as a LAN cable disconnection and an NIC malfunction).

Fig. 4.8: Flow of error detection by the IP monitor resource: when only one server detects an error (2)

(3) IP monitor resource 1 retries the monitoring up to three times.

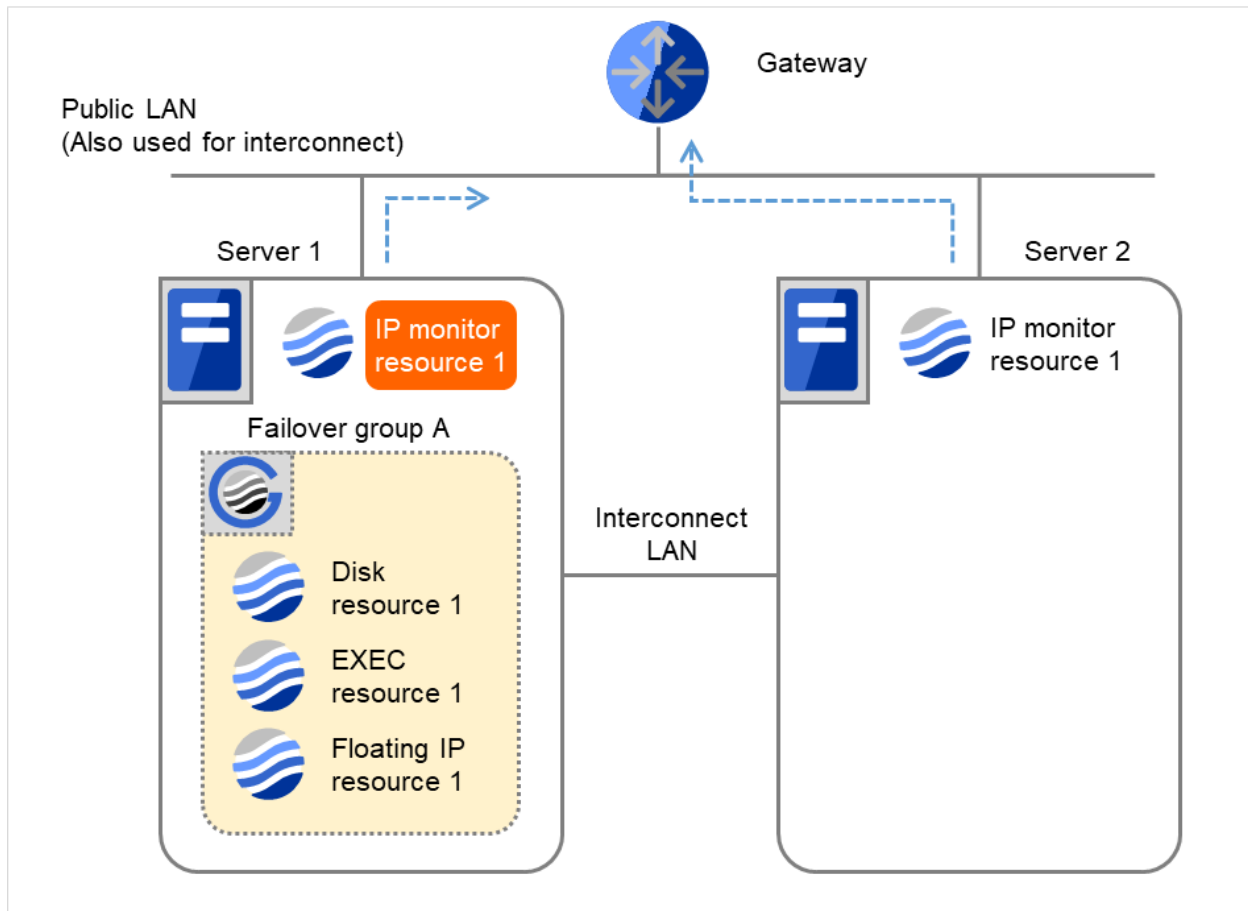

Fig. 4.9: Flow of error detection by the IP monitor resource: when only one server detects an error (3)

- (4) If the specified monitor retry count is exceeded, the recovery script starts to be executed on Server 1.  
**Recovery Script Execution Count** means how many times the recovery script is executed on each server.  
 This is the first execution of the recovery script on Server 1.  
 The recovery is not made on Server 2, because the status of Failover group A is **Already stopped**.

Fig. 4.10: Flow of error detection by the IP monitor resource: when only one server detects an error (4)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	0	0
Failover Count	0	0

- (5) On Server 1, if the specified **Recovery Script Execution Count** is exceeded, Failover group A starts to be reactivated.

**Reactivation Count** represents how many times the reactivation is done on each server.

This is the first reactivation on Server 1.

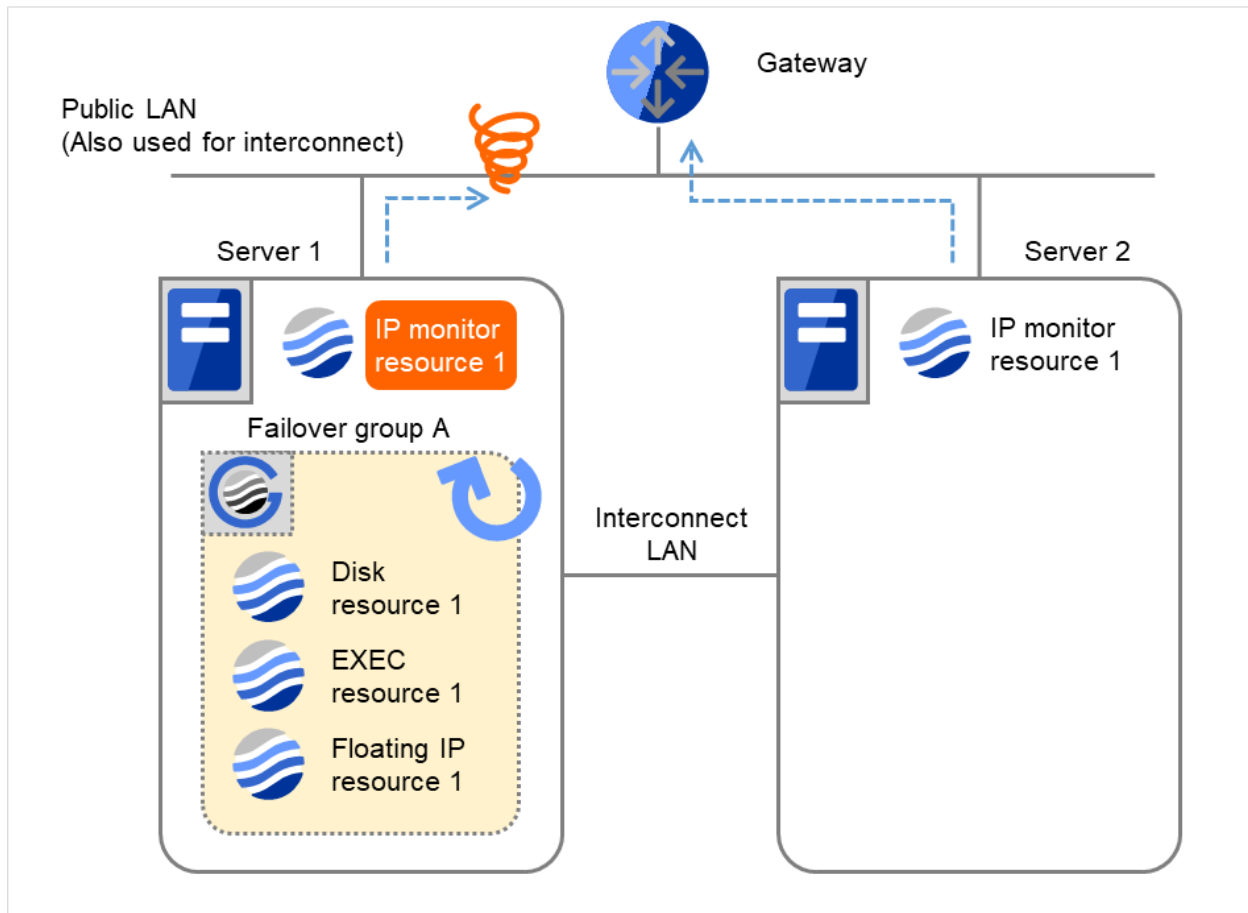

Fig. 4.11: Flow of error detection by the IP monitor resource: when only one server detects an error (5)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	0	0

- (6) On Server 1, if the specified threshold of reactivation is exceeded, Failover group A starts to be failed over.

**Failover Threshold** represents how many times the failover is performed on each server.

This is the first failover on Server 1.

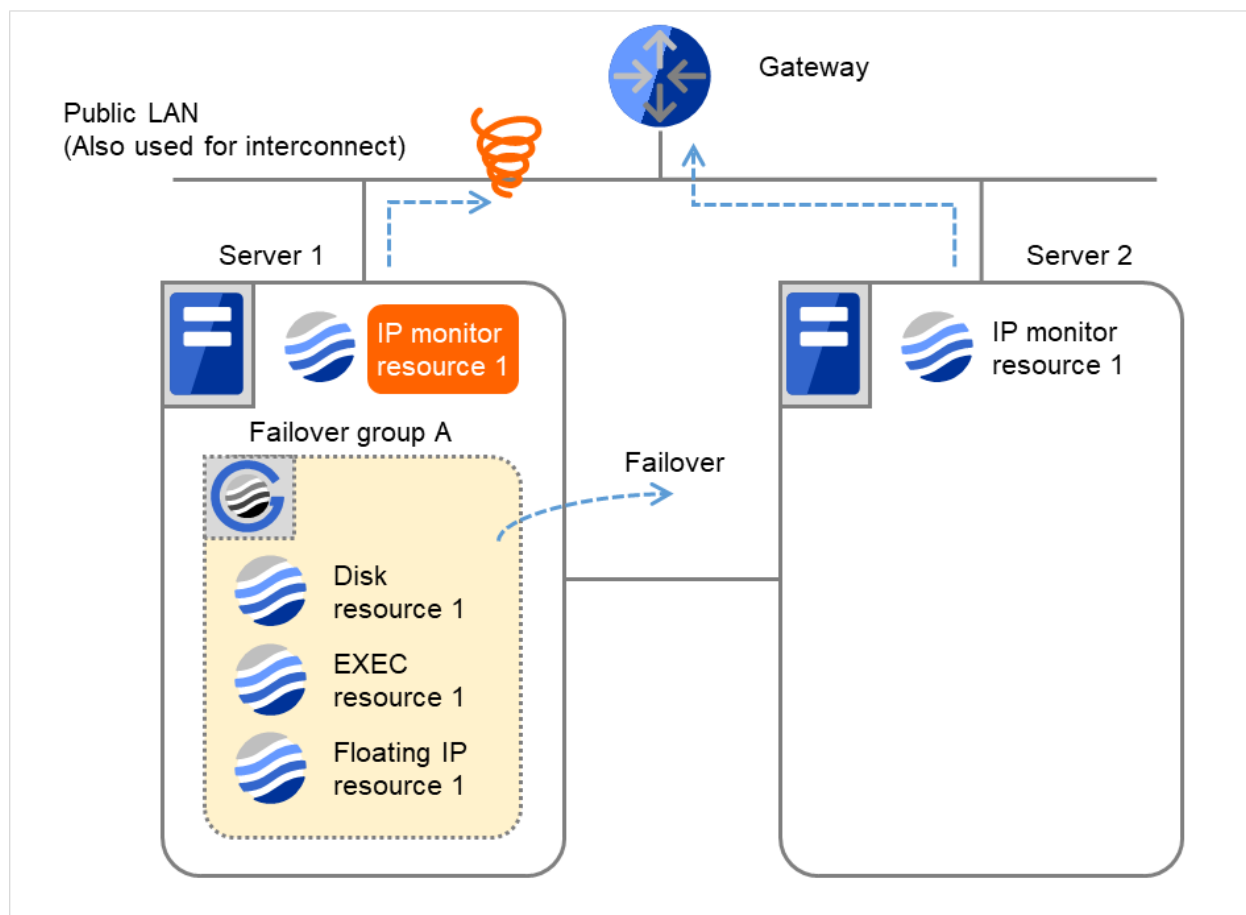

Fig. 4.12: Flow of error detection by the IP monitor resource: when only one server detects an error (6)

- (7) Failover group A is failed over from Server 1 to Server 2.  
On Server 2, the failover of Failover group A is completed.

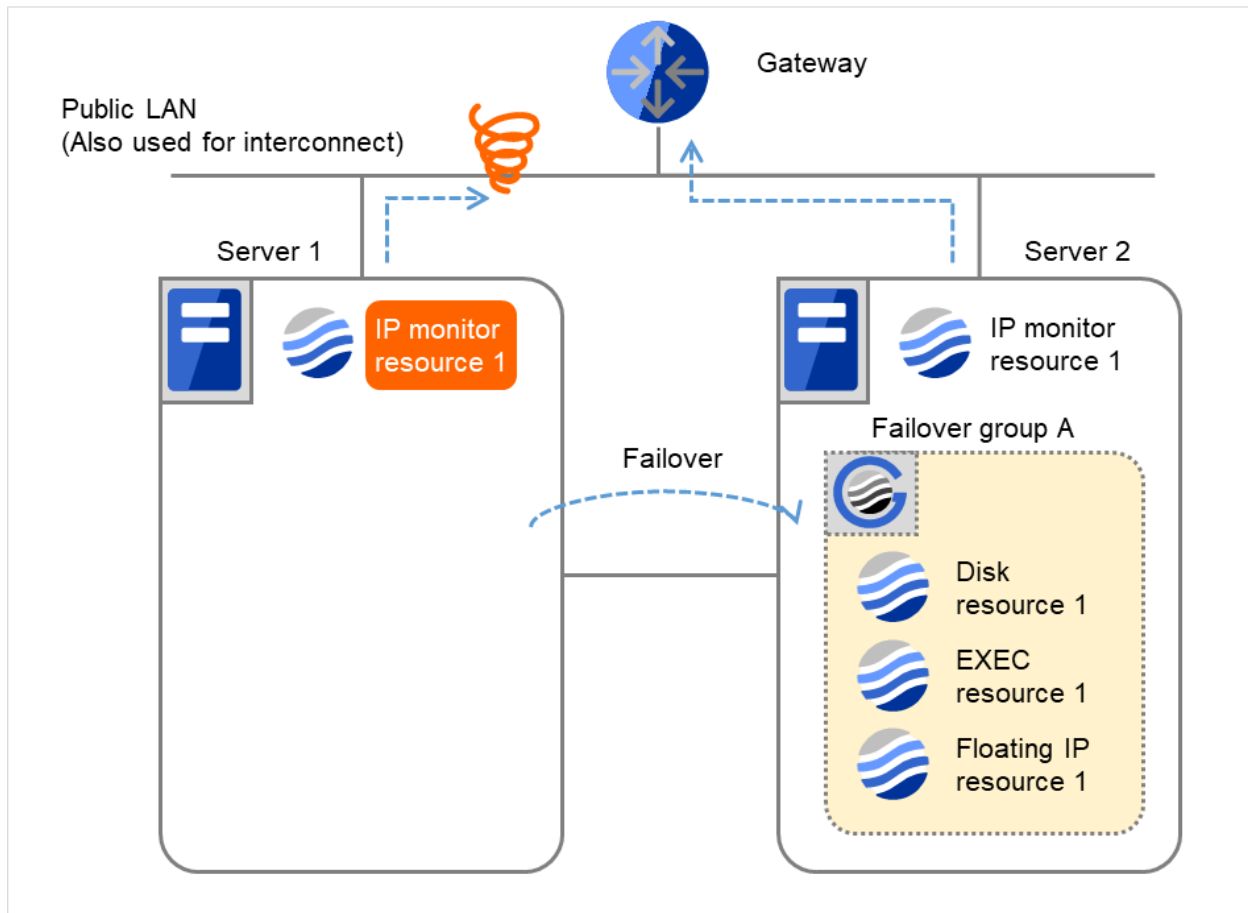

Fig. 4.13: Flow of error detection by the IP monitor resource: when only one server detects an error (7)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	1	0

In server2, the operation can continue by failover of the Failover Group A because the IP monitor resource 1 is running properly.

The following is an example of the process when both servers detect an error while the gateway is specified as an IP resource of the IP monitor resource.

Examples of behavior when the following values are set.

<Monitor>

Interval 30 sec

Timeout 30 sec

Retry Count 3 times

<Error detection>

Recovery Target Failover Group A

Recovery Script Execution Count 3 times

Maximum Reactivation Count 3 times

Maximum Failover Count 1 time

Final Action No Operation

- (1) The following figure shows an example of monitoring by the IP monitor resource on two servers.  
To check for the aliveness, IP monitor resource 1 accesses the gateway's IP address at the intervals.

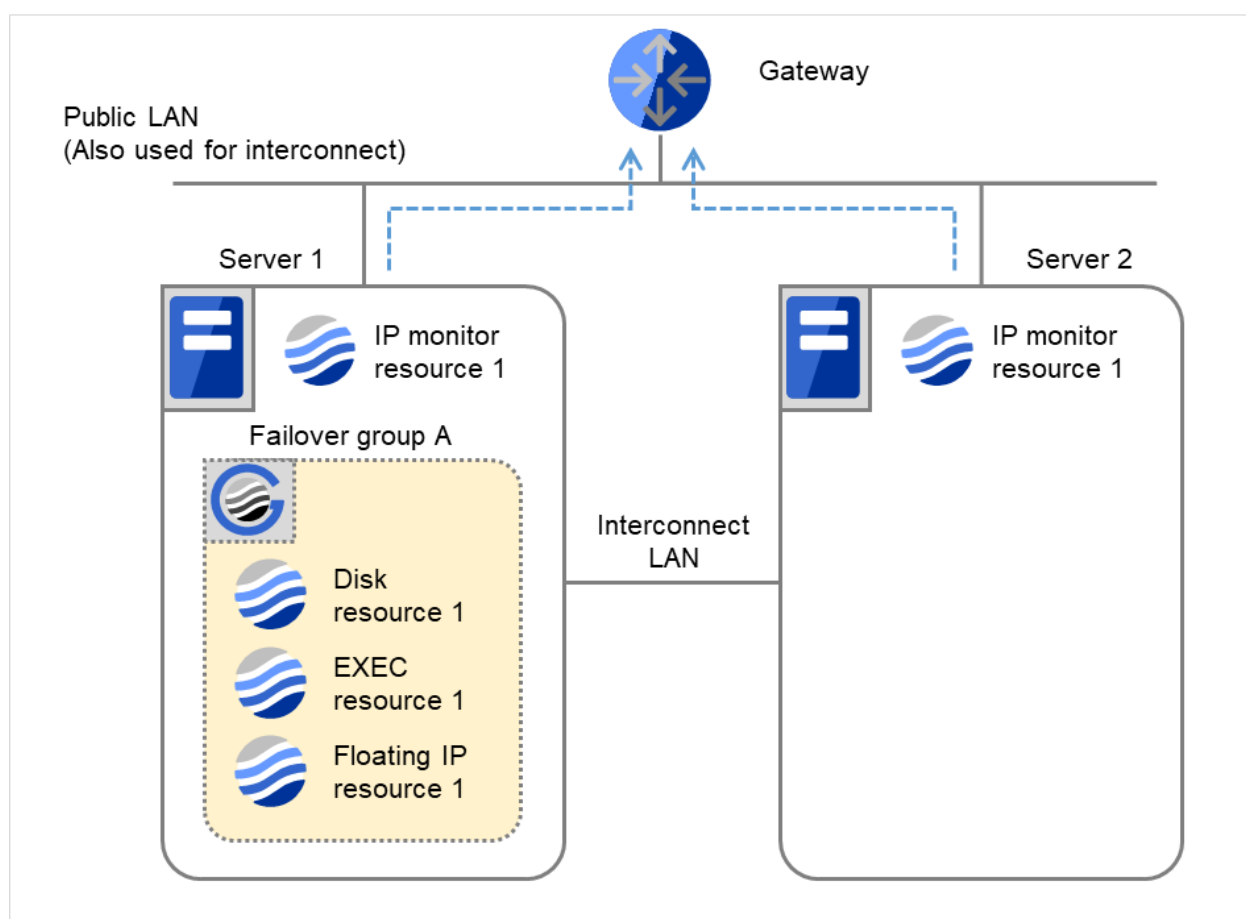

Fig. 4.14: Flow of error detection by the IP monitor resource: when both servers detect an error (1)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	0	0
Reactivation Count	0	0
Failover Count	0	0

- (2) IP monitor resource 1 detects an error (such as a LAN cable disconnection and an NIC malfunction) on Servers 1 and 2.

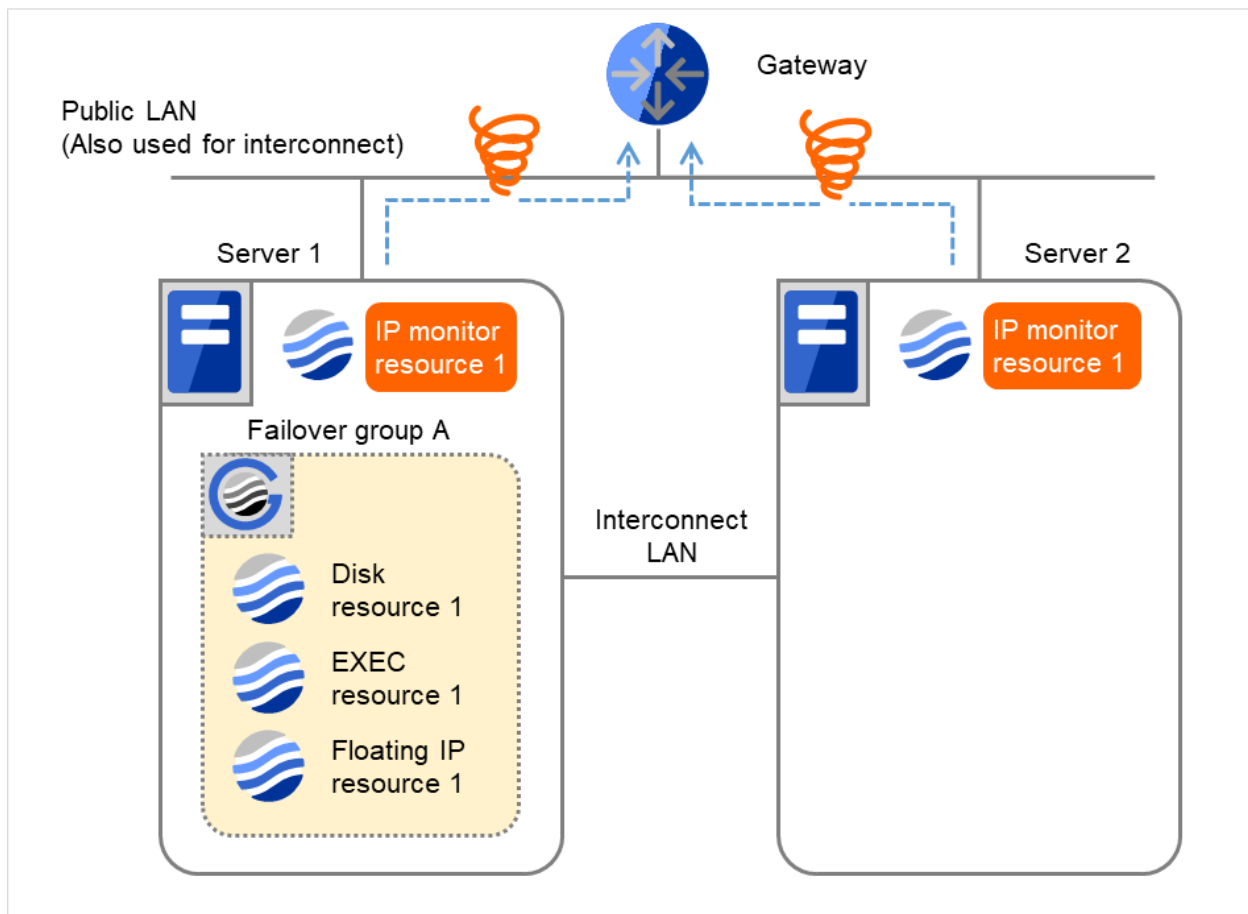

Fig. 4.15: Flow of error detection by the IP monitor resource: when both servers detect an error (2)

- (3) IP monitor resource 1 retries the monitoring up to three times.

Fig. 4.16: Flow of error detection by the IP monitor resource: when both servers detect an error (3)

- (4) If the specified monitor retry count is exceeded, the recovery script starts to be executed on Server 1.

**Recovery Script Execution Count** means how many times the recovery script is executed on each server.

This is the first execution of the recovery script on Server 1.

The recovery is not made on Server 2, because the status of Failover group A is **Already stopped**.

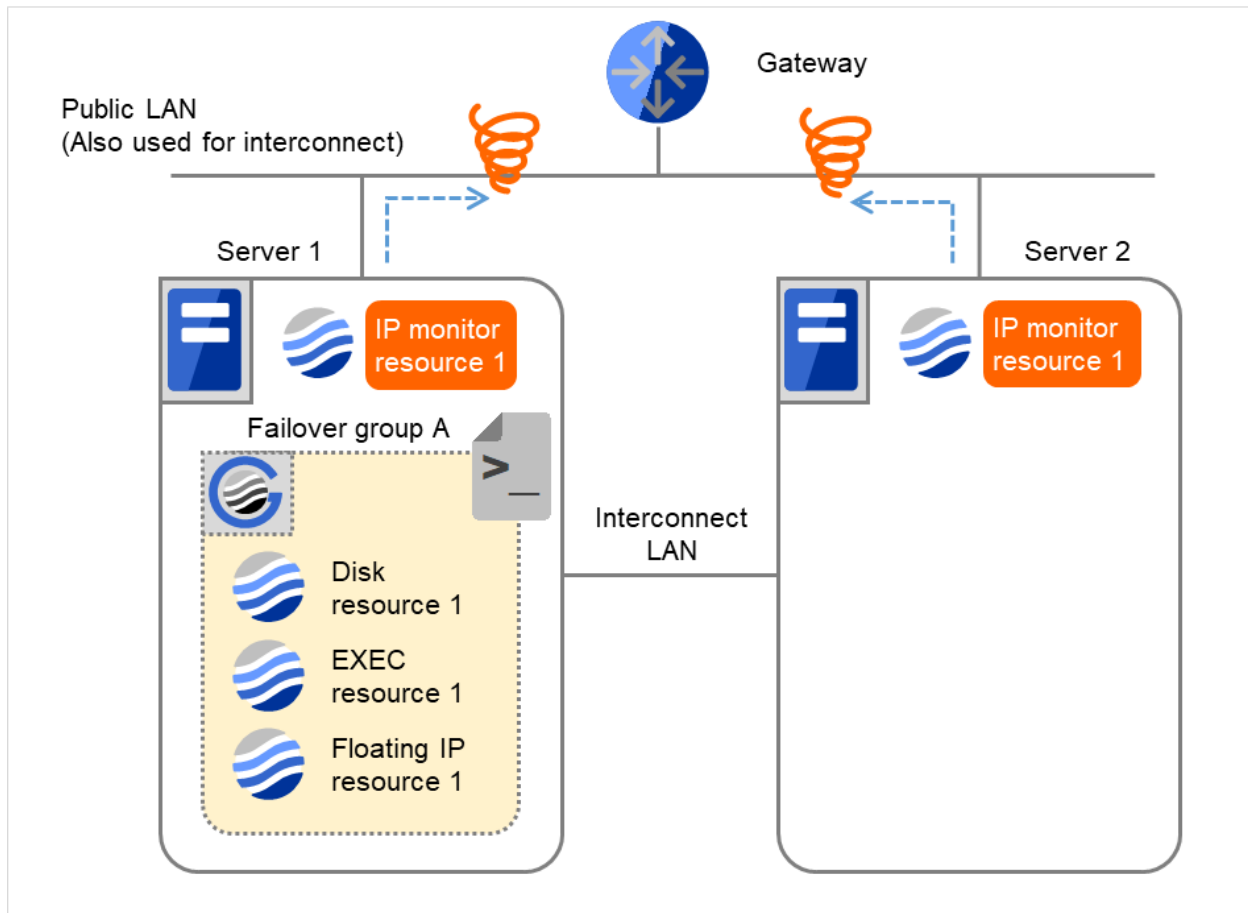

Fig. 4.17: Flow of error detection by the IP monitor resource: when both servers detect an error (4)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	0	0
Failover Count	0	0

- (5) On Server 1, if the specified **Recovery Script Execution Count** is exceeded, Failover group A starts to be reactivated.

**Reactivation Count** represents how many times the reactivation is done on each server.

This is the first reactivation on Server 1.

The recovery is not made on Server 2, because the status of Failover group A is **Already stopped**.

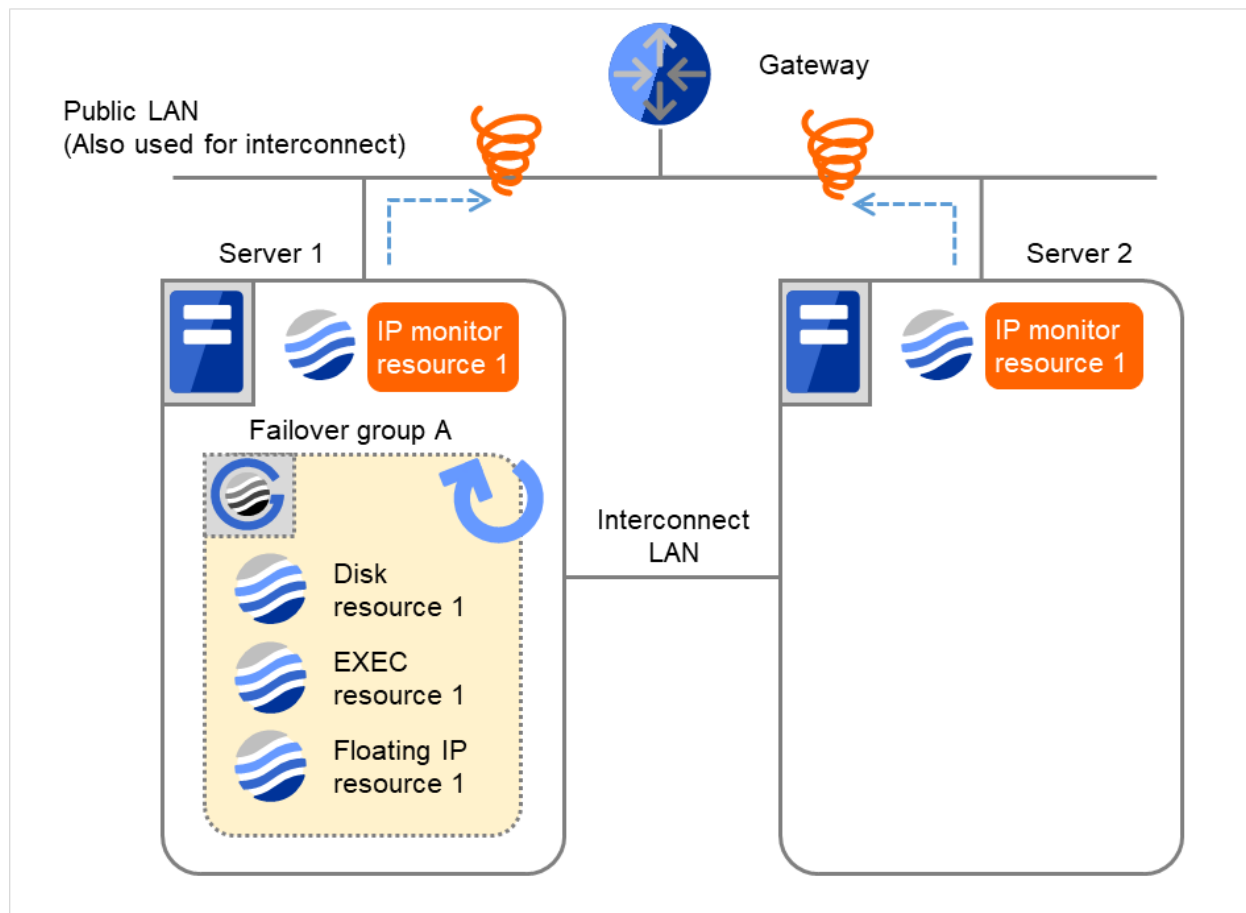

Fig. 4.18: Flow of error detection by the IP monitor resource: when both servers detect an error (5)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	0	0

- (6) On Server 1, if the specified threshold of reactivation is exceeded, Failover group A starts to be failed over.

**Failover Threshold** represents how many times the failover is performed on each server.

This is the first failover on Server 1.

The recovery is not made on Server 2, because the status of Failover group A is **Already stopped**.

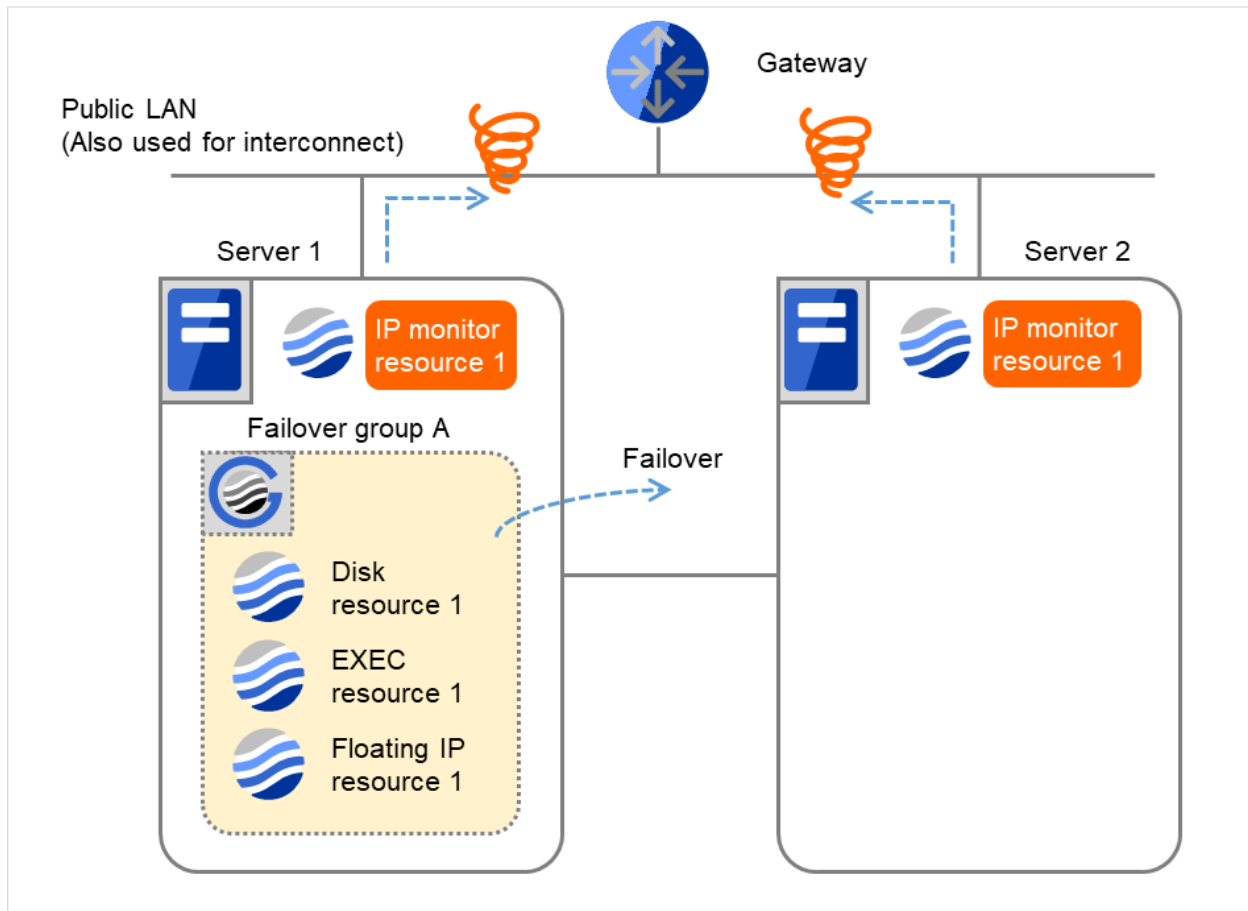

Fig. 4.19: Flow of error detection by the IP monitor resource: when both servers detect an error (6)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	1	0

- (7) Failover group A is failed over from Server 1 to Server 2.  
On Server 2, IP monitor resource 1 finds the error persisting.

Fig. 4.20: Flow of error detection by the IP monitor resource: when both servers detect an error (7)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	1	0

(8) IP monitor resource 1 retries the monitoring up to three times.

Fig. 4.21: Flow of error detection by the IP monitor resource: when both servers detect an error (8)

- (9) If the specified monitor retry count is exceeded by IP monitor resource 1 and the error persists, then executing the recovery script is retried up to three times.

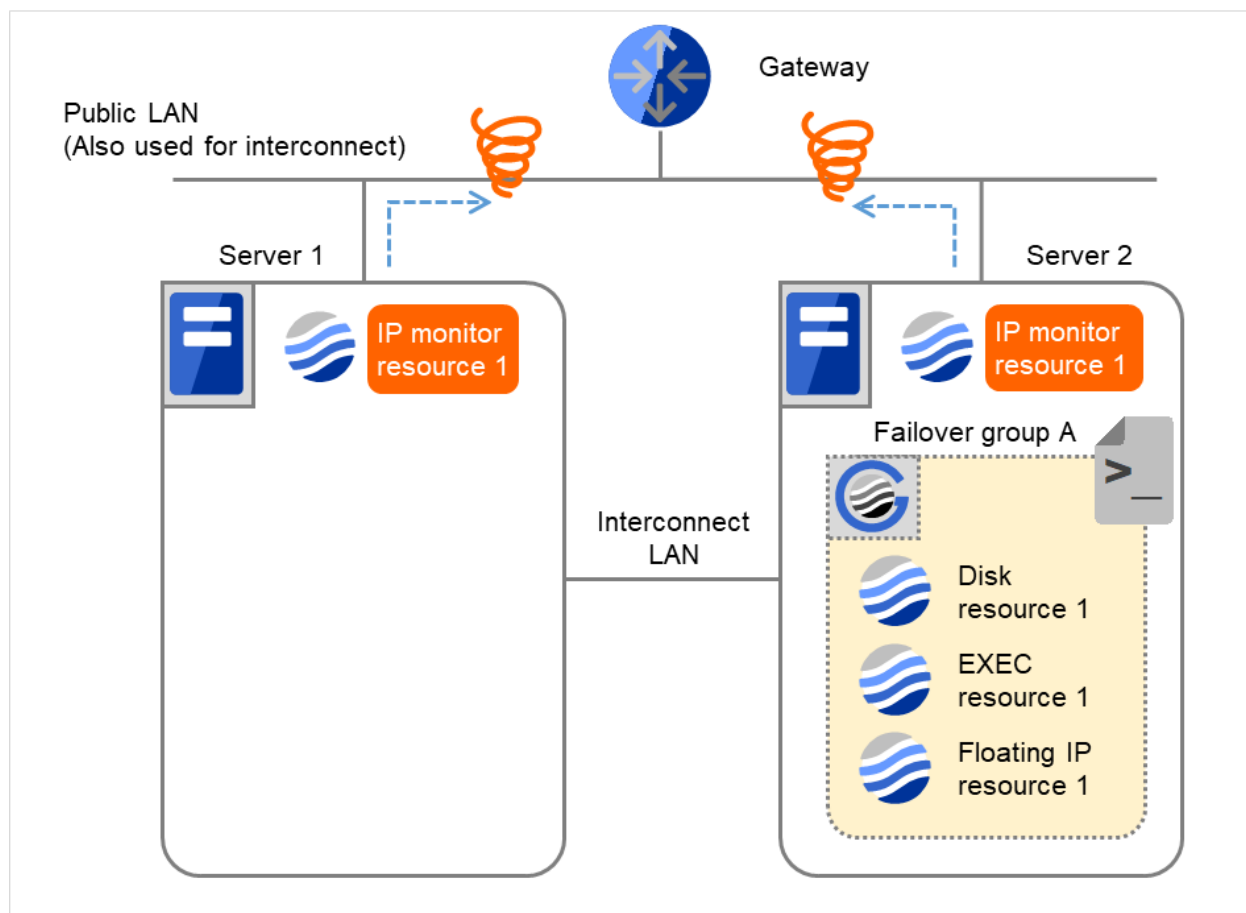

Fig. 4.22: Flow of error detection by the IP monitor resource: when both servers detect an error (9)

- (10) On Server 2, if the specified retry count is exceeded for the recovery script execution and the error persists, reactivating Failover group A is retried up to three times.

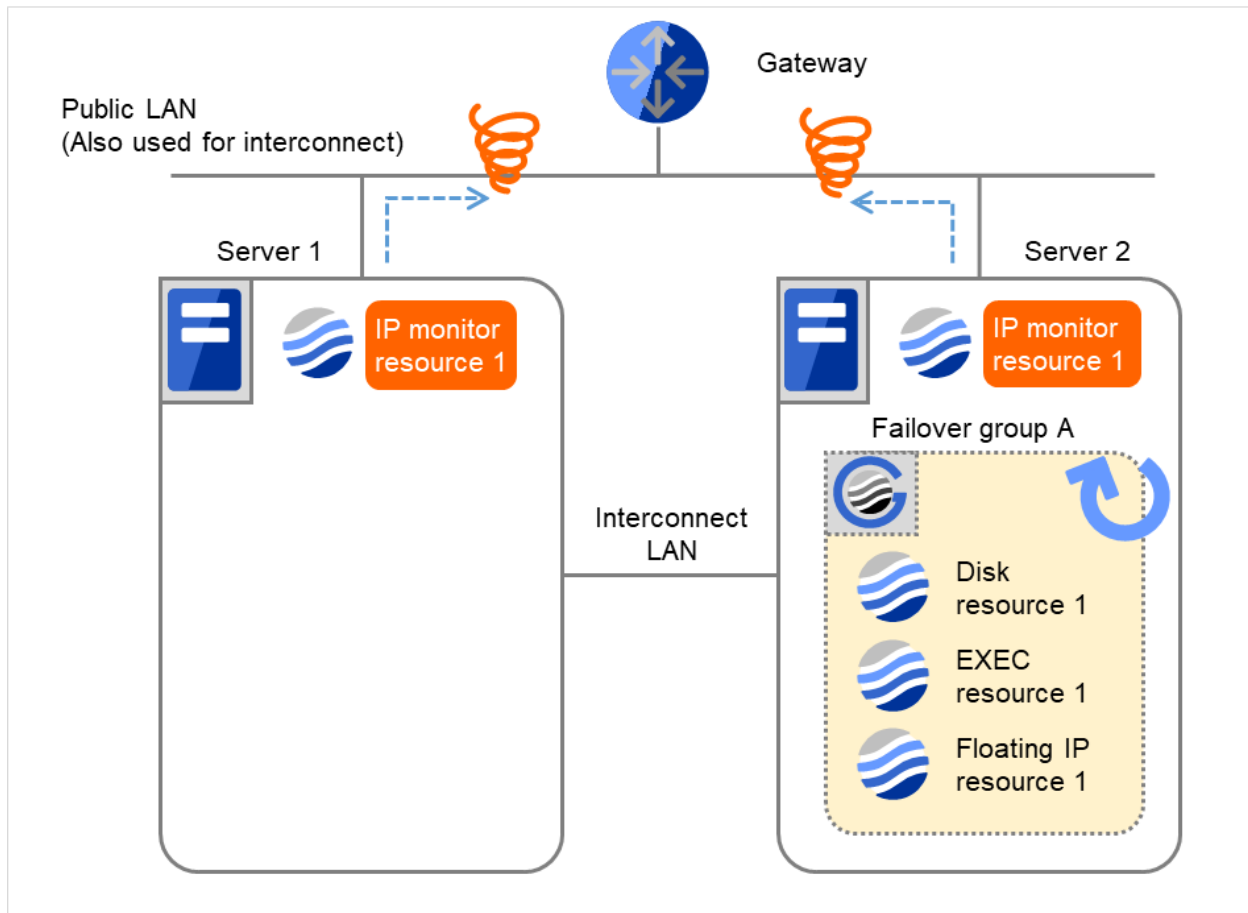

Fig. 4.23: Flow of error detection by the IP monitor resource: when both servers detect an error (10)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	3
Reactivation Count	3	3
Failover Count	1	0

- (11) On Server 2, if the specified reactivation retry count is exceeded, Failover group A starts to be failed over. This is the first failover on Server 2.

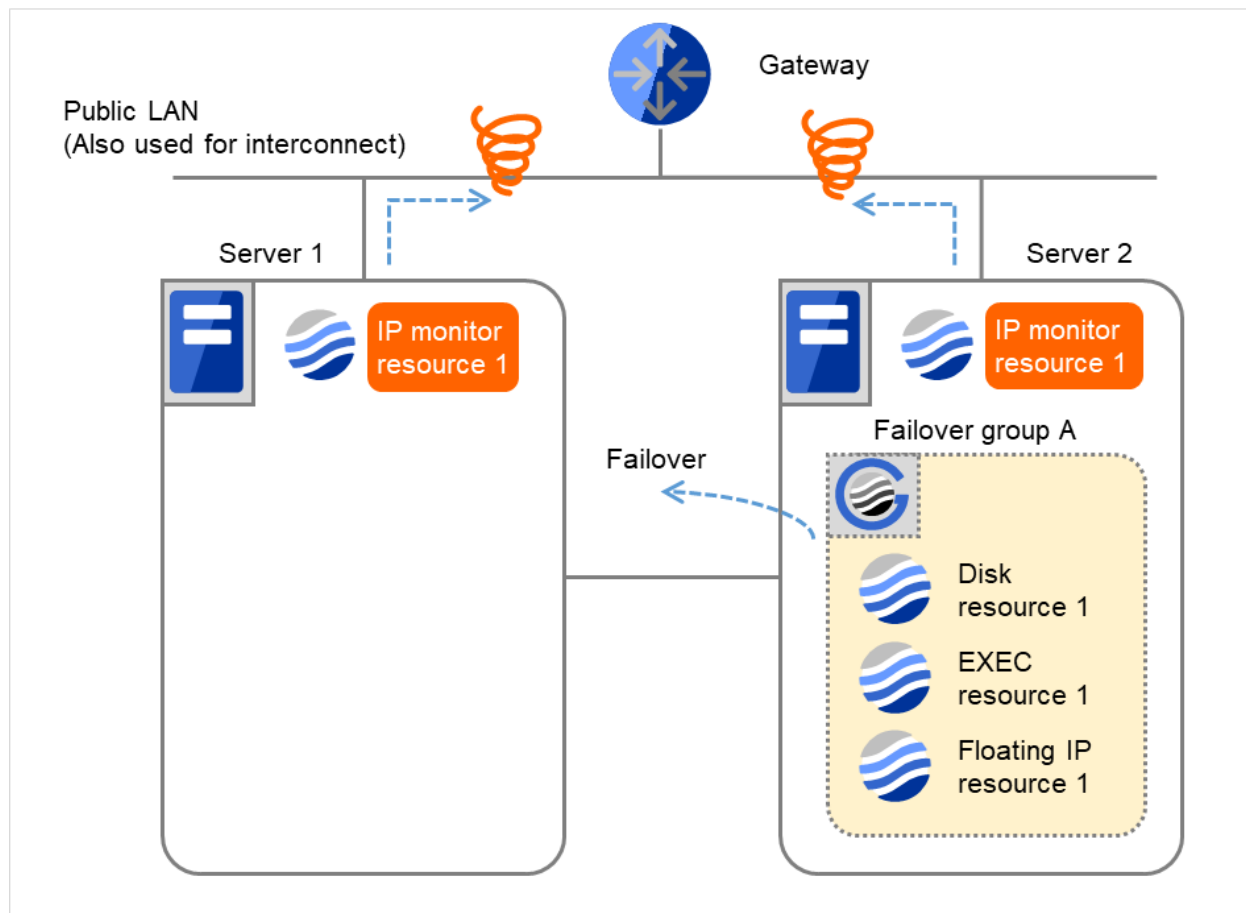

Fig. 4.24: Flow of error detection by the IP monitor resource: when both servers detect an error (11)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	3
Reactivation Count	3	3
Failover Count	1	1

- (12) Failover group A is failed over from Server 2 to Server 1.  
On Server 1, IP monitor resource 1 finds the error persisting.

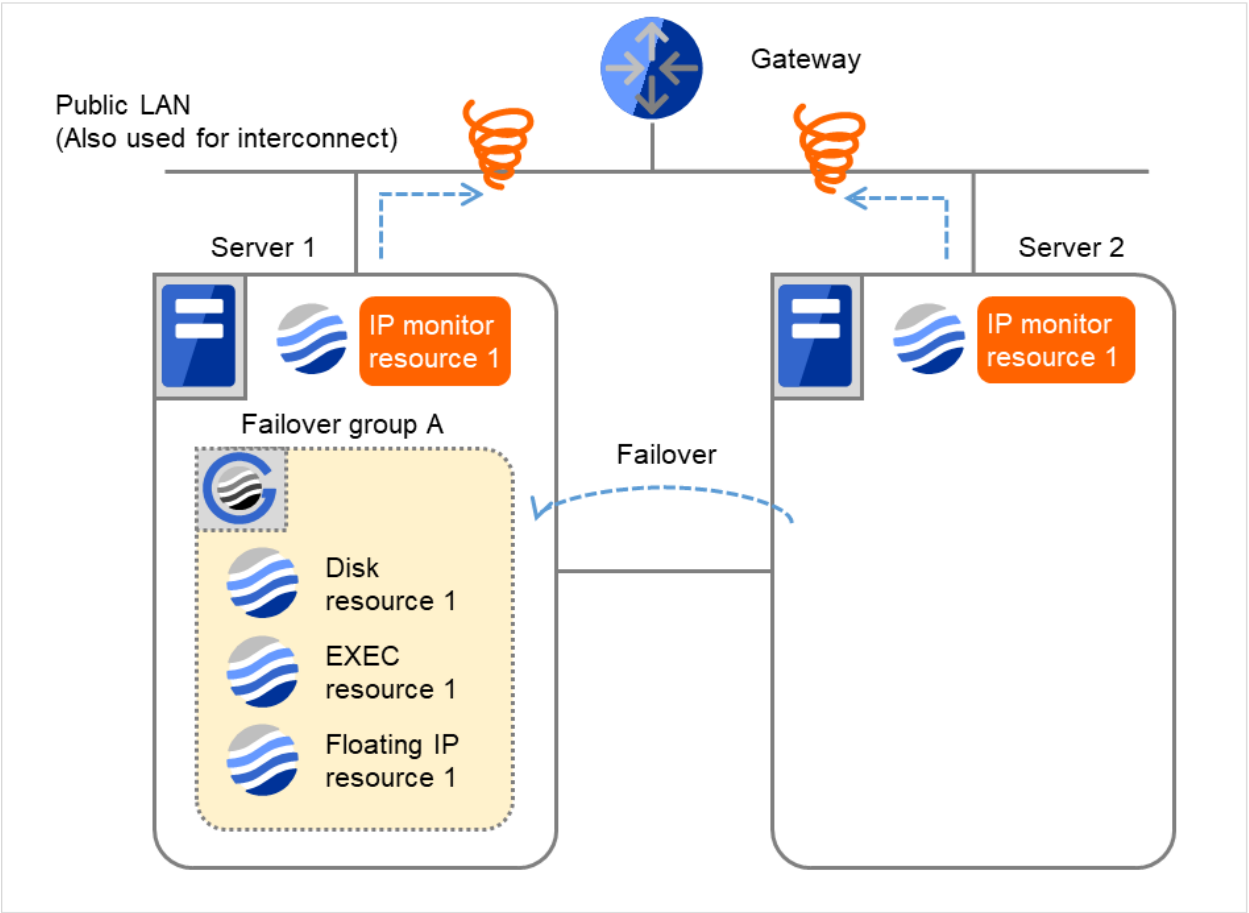

Fig. 4.25: Flow of error detection by the IP monitor resource: when both servers detect an error (12)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	3
Reactivation Count	3	3
Failover Count	1	1

(13) On Server 1, IP monitor resource 1 retries the monitoring up to three times.

Fig. 4.26: Flow of error detection by the IP monitor resource: when both servers detect an error (13)

- (14) If the specified monitor retry count is exceeded by Disk monitor resource 1 on Server 1 again, the reactivation is not performed. This is because its threshold is 3.

In addition, the specified **Final Action** is started. No failover is performed then, because **Failover Threshold** is set at 1.

On Server 1, the final action of IP monitor resource 1 is started.

**Final Action** means the action to be taken after the specified failover retry count is exceeded.

Fig. 4.27: Flow of error detection by the IP monitor resource: when both servers detect an error (14)

### Additional Information

When the status of the monitor target becomes normal from an error and the monitor resource detects the change, the reactivation count and failover count are reset to zero (0). When an error is detected next time, the process will be exactly the same as what has been described up to here.

The description up to here assumed the interconnect LANs are working properly.

If all interconnect LANs are disconnected, internal communications with other servers are blocked. As a result, even if an error is detected on a monitor target, failover of groups fails.

To fail over a group when all interconnect LANs are disconnected, you can choose to shut down the server where an error is detected. This will allow other servers to detect the server is shut down and to start failover of the group.

The following is an example of the process when an error is detected while all interconnect LANs are disconnected.

Configuration

<Monitor>

Interval 30 seconds  
Timeout 30 seconds  
Retry Count 3 times

<Error detection>

Recovery Object Failover Group A  
Recovery Script Execution Count 3 times  
Maximum Reactivation Count 3 times  
Maximum Failover Count 1 time  
Final Action Stop cluster daemon and shutdown OS

Reactivation for the recovery target is same as the situation when the interconnect LANs are working properly. The description begins from the failover on server1, which requires interconnect LANs.

- (1) The following figure shows an example of monitoring by the IP monitor resource on two servers.  
The reactivation is being retried on Server 1 while all interconnect LANs are disconnected.

Fig. 4.28: Flow of error detection by the IP monitor resource: when all interconnect LANs are disconnected (1)

	Server 1 IP monitor resource 1
Recovery Script Execution Count	3
Reactivation Count	3
Failover Count	0

- (2) If the reactivation threshold is exceeded on Server 1, Failover group A starts to be failed over. However, it fails due to the disconnected interconnect LANs and therefore blocked internal communication.

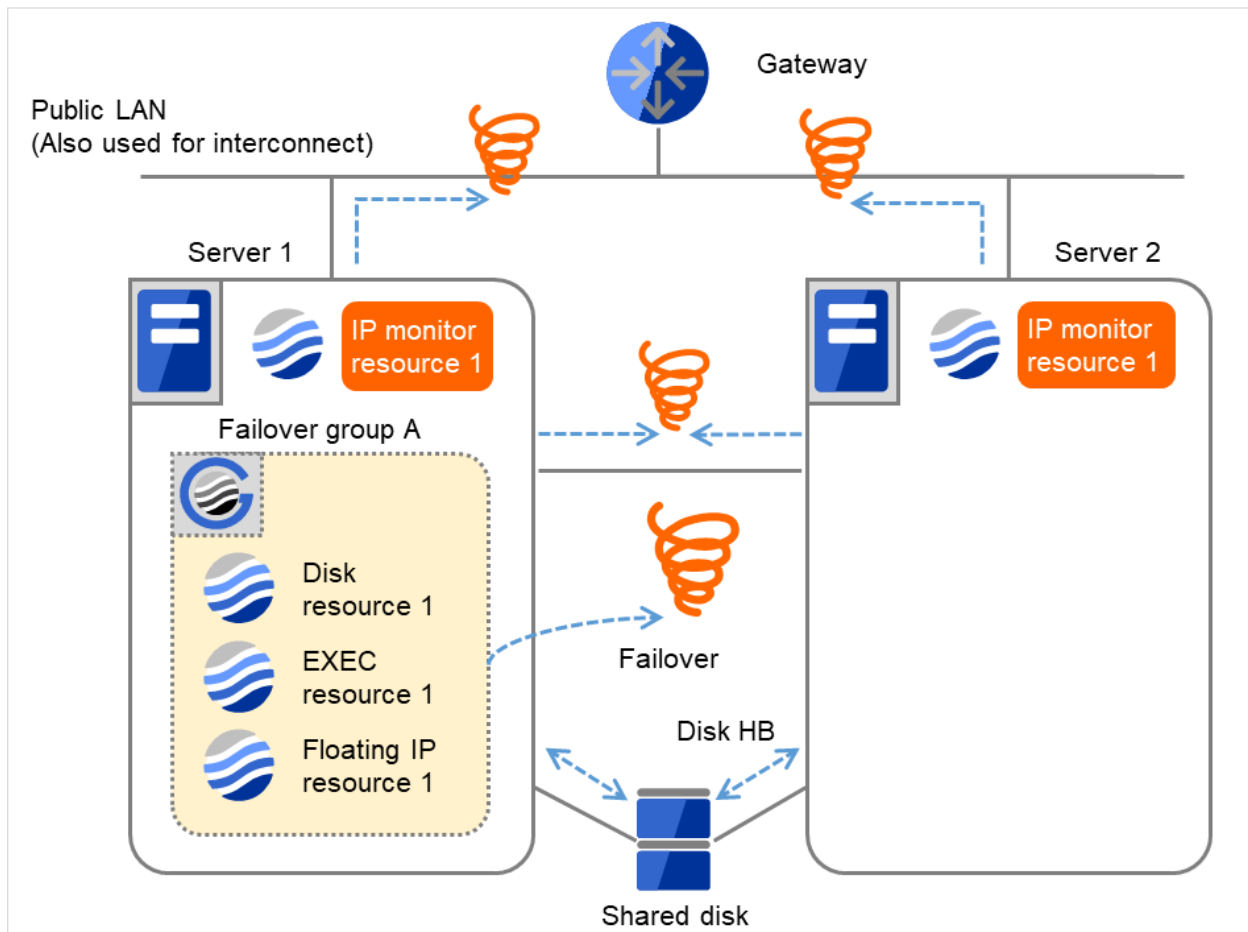

Fig. 4.29: Flow of error detection by the IP monitor resource: when all interconnect LANs are disconnected (2)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	3
Reactivation Count	3	0
Failover Count	1	0

- (3) On Server 1, if the failover threshold is exceeded, the **Final Action** is taken: The cluster daemon is stopped and the OS is shut down.

After Server 1 crashes, Failover group A starts to be failed over in accordance with the failover policy.

**Final Action** means the action to be taken after the specified failover retry count is exceeded.

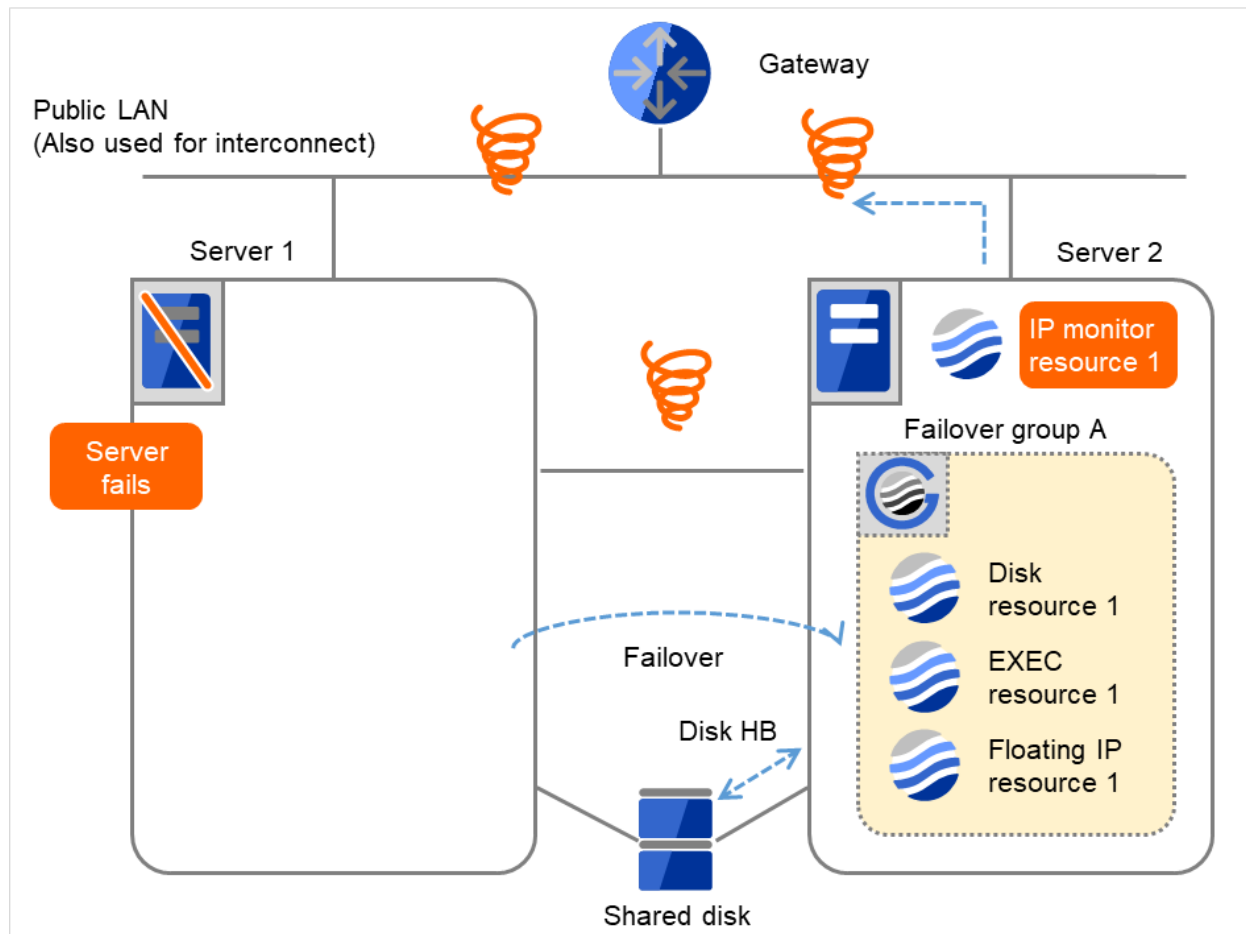

Fig. 4.30: Flow of error detection by the IP monitor resource: when all interconnect LANs are disconnected (3)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	1	0

- (4) On Server 2, if IP monitor resource 1 finds the error persisting, Failover group A starts to be reactivated as on Server 1.

If an error occurs during the reactivation on Server 2 as well, a failover is to be tried in normal cases.

However, this failover cannot be done, because no failover destination exists.

On Server 2, if the failover threshold is exceeded, the final action is taken as on Server 1.

Fig. 4.31: Flow of error detection by the IP monitor resource: when all interconnect LANs are disconnected (4)

#### 4.1.7 Returning from monitor error (Normal)

When return of the monitor resource is detected during or after recovery actions following the detection of a monitoring error, counts for the thresholds shown below are reset:

- Recovery Script Execution Count
- Reactivation Count
- Failover Count

Whether or not to execute the final action is reset (execution required).

The following pages describe what will be executed from the point when the final action as described in "*Action when an error is detected by monitor resource*" executed and another monitoring error occurs after monitoring returns to normal.

Examples of behavior when the following values are set.

Configuration

<Monitor>

Interval 30 sec

Timeout 30 sec  
Retry Count 3 times

<Error detection>

Recovery Target Failover Group A

Recovery Script Execution Count 3 times

Maximum Reactivation Count 3 times

Maximum Failover Count 1 time

Final Action Stop Failover Group

- (1) The following figure shows an example of monitoring by the IP monitor resource on two servers.  
After all recovery actions are taken, a monitoring error persists.  
On Server 1, the final action of IP monitor resource 1 was taken.

Fig. 4.32: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (1)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	3
Reactivation Count	3	3
Failover Count	1	1

- (2) When the gateway is restored, IP monitor resource 1 finds the situation normal.  
This resets the reactivation count and failover count.

Fig. 4.33: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (2)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	0	0
Reactivation Count	0	0
Failover Count	0	0

(3) IP monitor resource 1 has detected an error again.

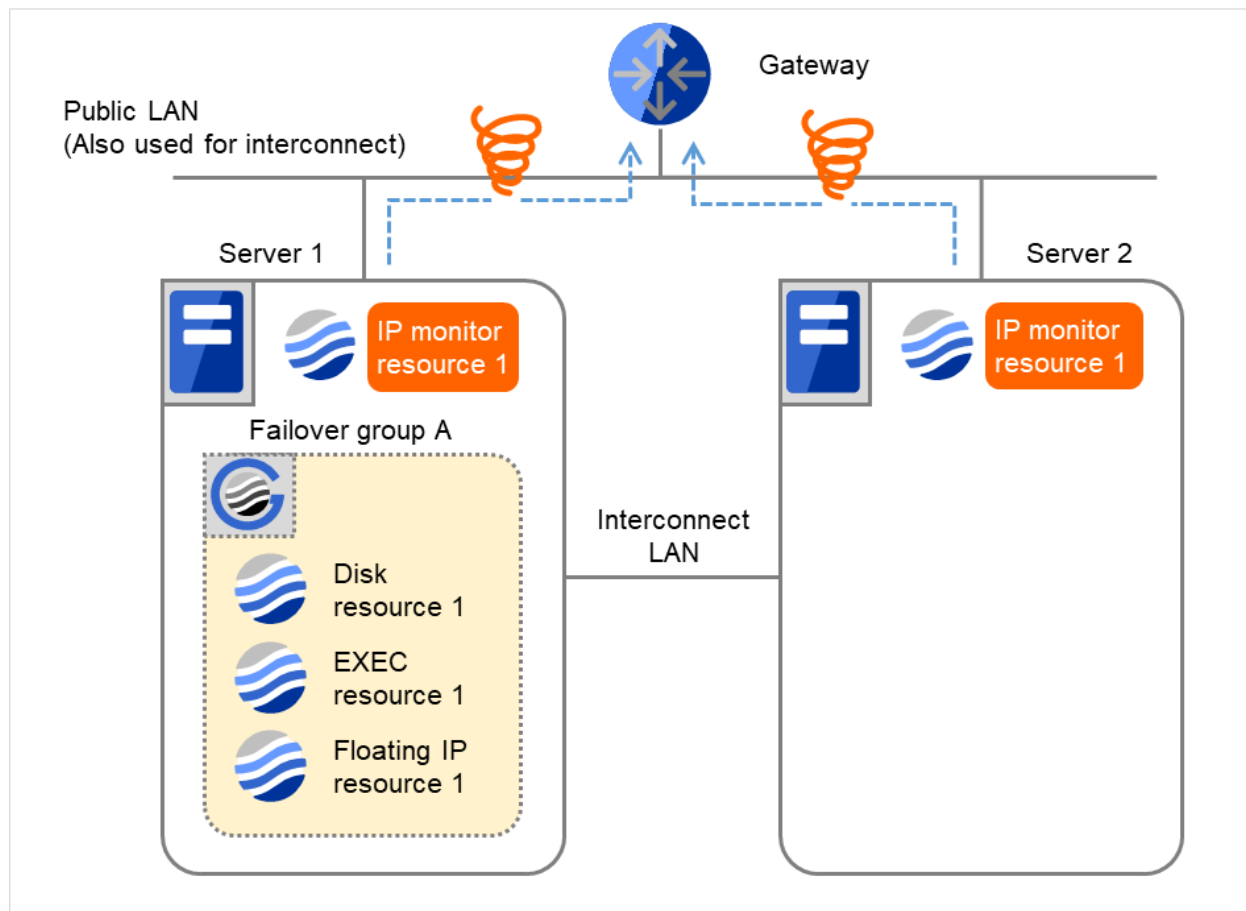

Fig. 4.34: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (3)

(4) IP monitor resource 1 retries the monitoring up to three times.

**Retry Count** means that on this server.

Fig. 4.35: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (4)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	0	0
Reactivation Count	0	0
Failover Count	0	0

- (5) If the specified monitor retry count is exceeded, the recovery script starts to be executed on Server 1.  
**Recovery Script Execution Count** means how many times the recovery script is executed on each server.  
 This is the first execution of the recovery script on Server 1.  
 The recovery is not made on Server 2, because the status of Failover group A is **Already stopped**.

Fig. 4.36: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (5)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	0	0
Failover Count	0	0

- (6) On Server 1, if the specified **Recovery Script Execution Count** is exceeded, Failover group A starts to be reactivated.

**Reactivation Count** represents how many times the reactivation is done on each server.

This is the first reactivation on Server 1.

The reactivation is done again, due to the reset reactivation count through the detection of the normalized target monitoring resource.

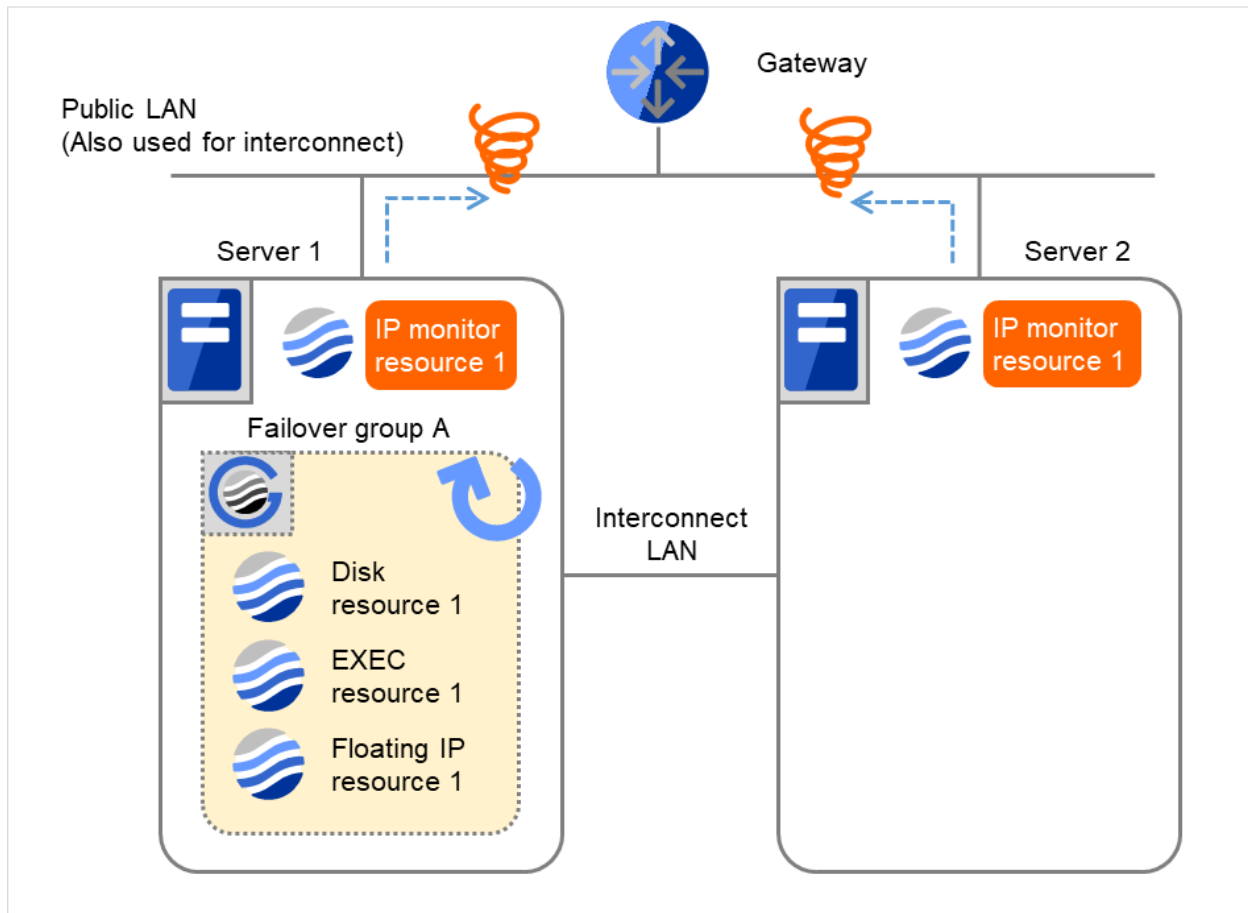

Fig. 4.37: Flow of error detection by the IP monitor resource: normally returning from a monitoring error (6)

	Server 1 IP monitor resource 1	Server 2 IP monitor resource 1
Recovery Script Execution Count	3	0
Reactivation Count	3	0
Failover Count	0	0

Reactivation is executed again because it has been detected that the status of the monitor target resource became normal and reactivation count has been reset before.

### **4.1.8 Activation and deactivation error of recovery target when executing recovery operation**

When the monitoring target of the monitor resource is the device used for the group resource of the recovery target, an activation/deactivation error of the group resource may be detected during recovery when a monitoring error is detected.

The following is an example of the recovery progress when the same device is specified as the monitor target of the disk monitor resource and the disk resource of the Failover Group A:

Configuration of the disk monitor resource

<Monitor>

Interval 60 seconds

Timeout 120 seconds

Retry Count 0 times

<Error detection>

Recovery Target Failover Group A

Recovery Script Execution Count 0 times

Maximum Reactivation Count 0 times

Maximum Failover Count 1 time

Final Action Stop Failover Group

<Parameter>

Method TUR

Configuration of the failover group A: disk resource

<Activation error>

Activation retry Threshold 0 times

Failover Threshold 1 time

Final Action No Operation (Next resources are not activated)

<Deactivation abnormality>

Deactivation Retry Threshold 0 times

Final Action Stop cluster daemon and shutdown OS

The reactivation threshold of the monitor resource and the activation retry threshold of the group resource are not mentioned in the following diagrams because they are set to zero (0).

(1) The following figure shows an example of monitoring by the disk monitor resource on two servers.

On Servers 1 and 2, Disk monitor resource 1 and Failover group A start to be activated.

At the intervals, ioctl TUR is executed on the device.

Fig. 4.38: Flow of error detection by the disk monitor resource (1)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	0	0
Disk resource 1 Failover Count	0	0

- (2) On Servers 1 and 2, Disk monitor resource 1 detects an error: failure in TUR ioctl.  
Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

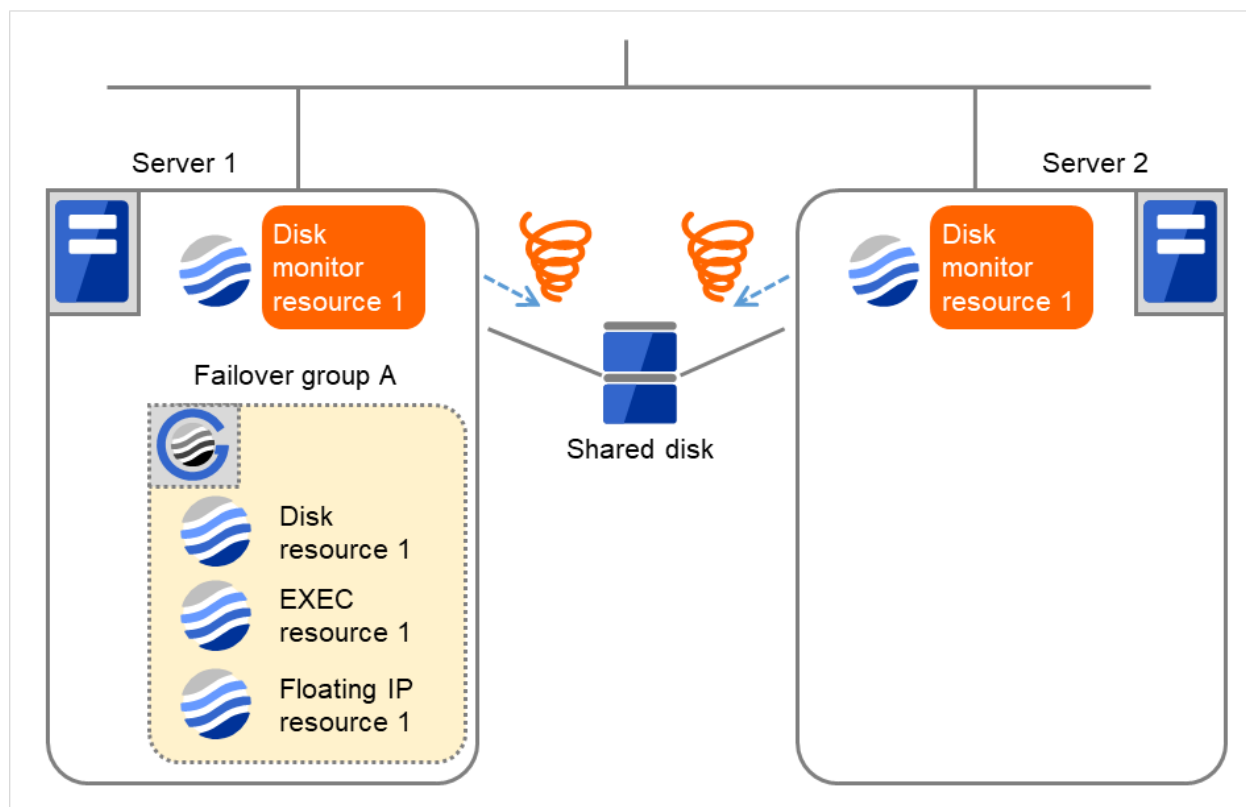

Fig. 4.39: Flow of error detection by the disk monitor resource (2)

- (3) Due to the error detected by Disk monitor resource 1 on Server 1, Failover group A starts to be failed over. The failover threshold of the monitor resource means how many times the failover is performed on each server. This is the first failover on Server 1.

Fig. 4.40: Flow of error detection by the disk monitor resource (3)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	0
Disk resource 1 Failover Count	0	0

- (4) On Server 2, due to the failover, activating Disk resource 1 fails (such as an fsck error and a mount error). Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

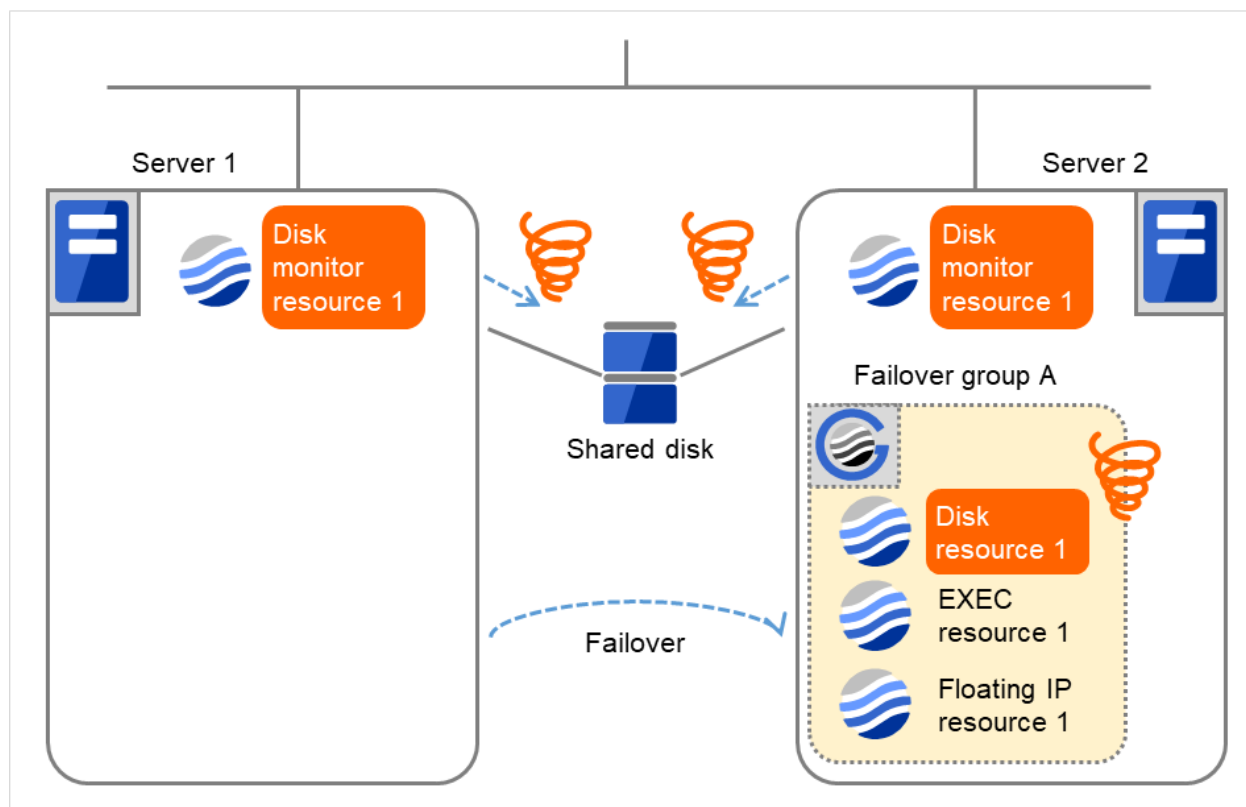

Fig. 4.41: Flow of error detection by the disk monitor resource (4)

- (5) Due to the activation failure of Disk resource 1 on Server 2, Failover group A starts to be failed over. The failover threshold of the group resource means how many times the failover is performed on each server. This is the first failover on Server 2.

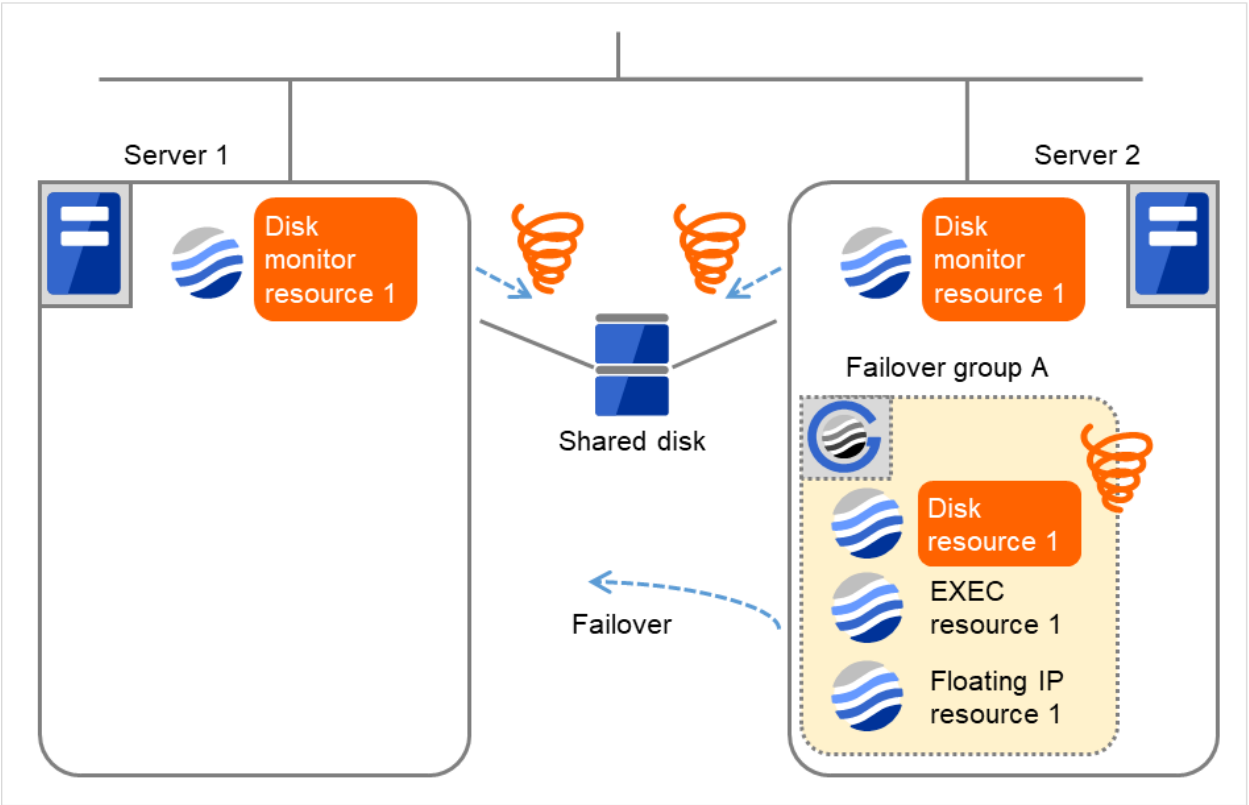

Fig. 4.42: Flow of error detection by the disk monitor resource (5)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	0
Disk resource 1 Failover Count	0	1

- (6) Although the error was detected by Disk monitor resource 1 on Server 2 as well as on Server 1, the recovery is not made. This is because the recovery target, Failover group A, is being started.

For information about the conditions on which the monitor resource takes recovery action on the recovery target, refer to *"Action when an error is detected by monitor resource"*.

On Server 1, due to the failover, activating Disk resource 1 fails (such as an fsck error and a mount error). Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

Fig. 4.43: Flow of error detection by the disk monitor resource (6)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	0
Disk resource 1 Failover Count	0	1

- (7) Due to the activation failure of Disk resource 1 on Server 1, Failover group A starts to be failed over. This is the first failover on Server 1. Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

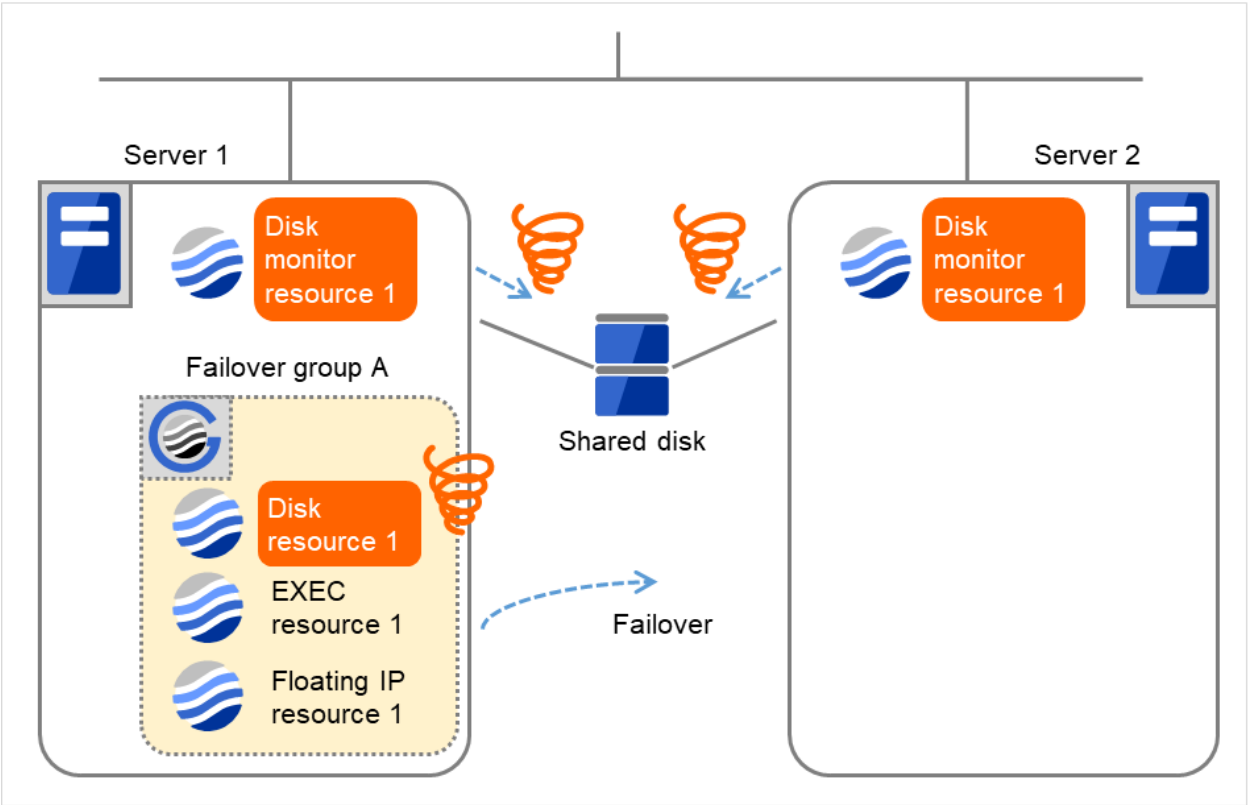

Fig. 4.44: Flow of error detection by the disk monitor resource (7)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	0
Disk resource 1 Failover Count	1	1

- (8) On Server 2, due to the failover, activating Disk resource 1 fails (such as an fsck error and a mount error). Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

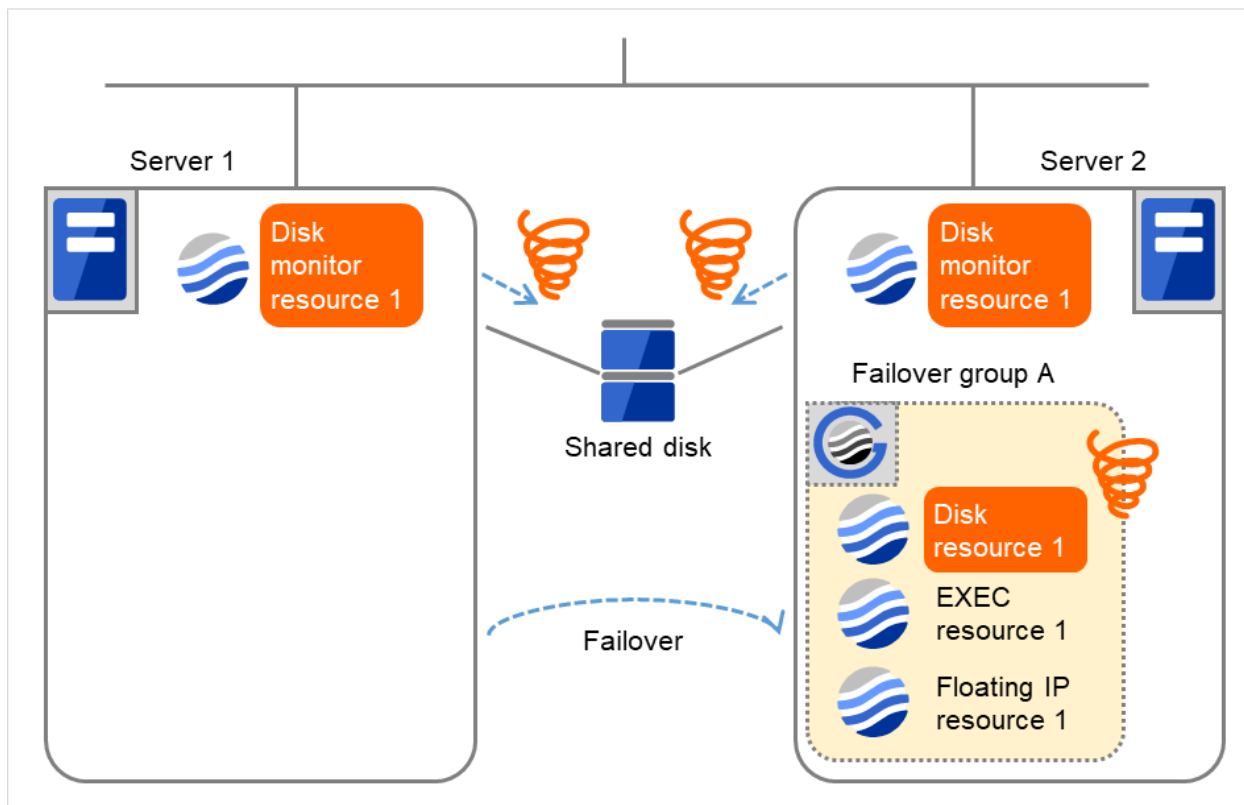

Fig. 4.45: Flow of error detection by the disk monitor resource (8)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	0
Disk resource 1 Failover Count	1	1

- (9) On Server 2, the final action is taken because the specified failover count is exceeded through the activation failure of Disk resource 1.  
However, since the specified final action is **No Operation (Next resources are not activated)**, the rest of the group resources in Failover group A is not activated. Therefore, the startup process abends.

Fig. 4.46: Flow of error detection by the disk monitor resource (9)

- (10) Due to the error detected by Disk monitor resource 1 on Server 2, Failover group A starts to be failed over. This is the first failover on Server 2.

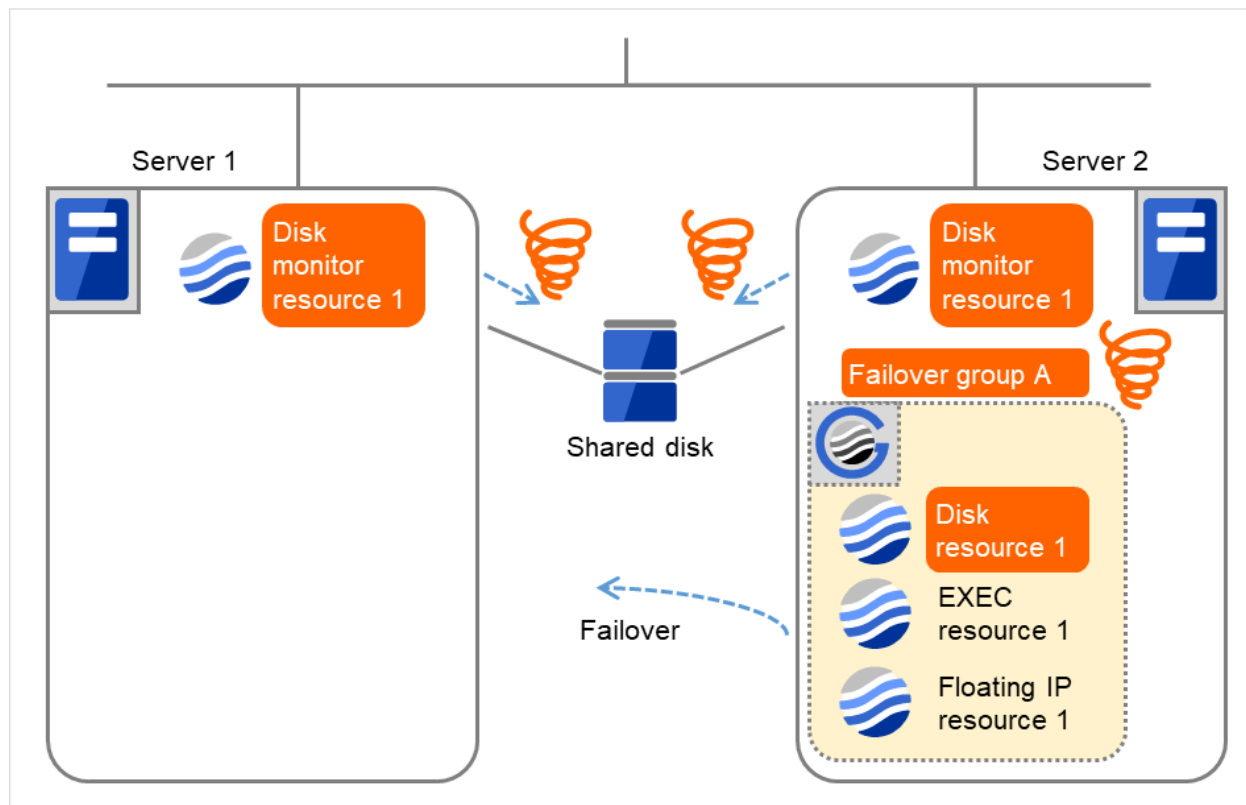

Fig. 4.47: Flow of error detection by the disk monitor resource (10)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	1
Disk resource 1 Failover Count	1	1

- (11) On Server 1 as well as on Server 2, the final action is taken because the specified failover count is exceeded through the activation failure of Disk resource 1.
- However, since the specified final action is **No Operation (Next resources are not activated)**, the rest of the group resources in Failover group A is not activated. Therefore, the startup process abends.
- Depending on the error location of the disk device, the error may be detected during the deactivation of the disk resource.

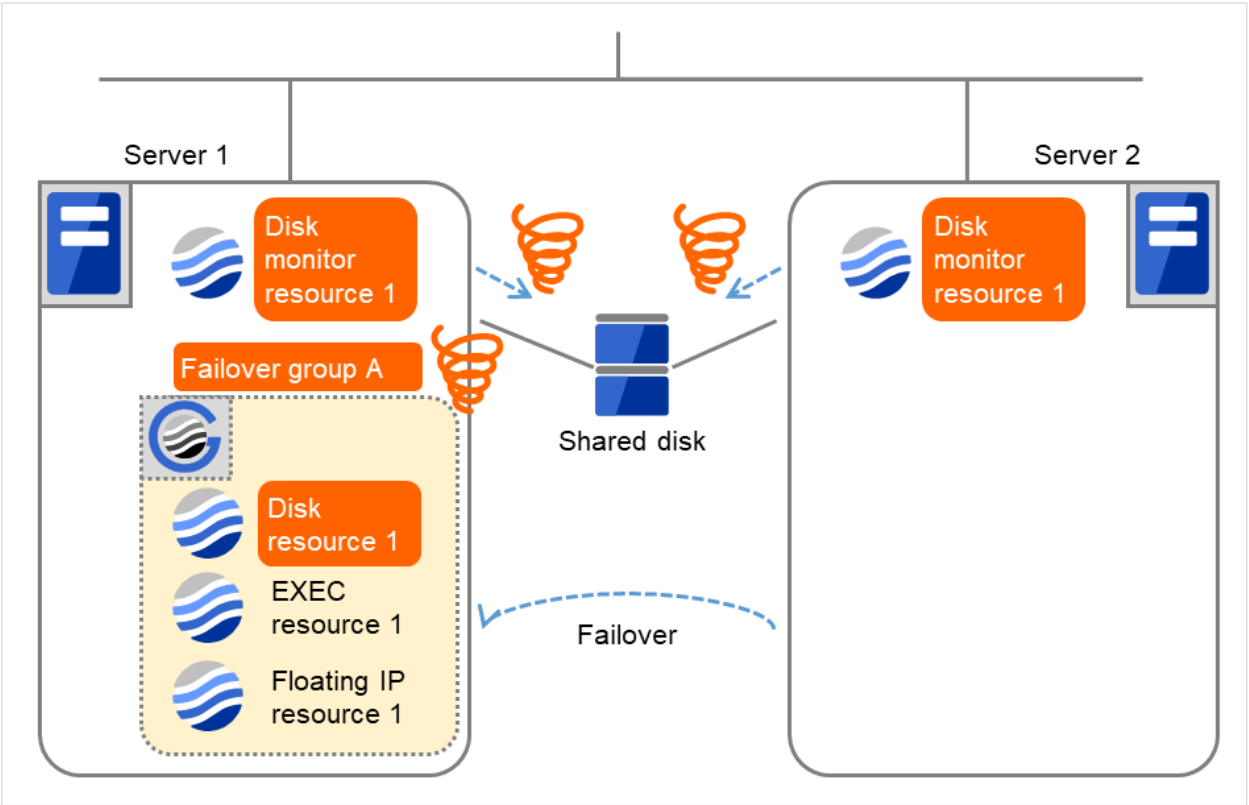

Fig. 4.48: Flow of error detection by the disk monitor resource (11)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	1
Disk resource 1 Failover Count	1	1

- (12) On Server 1, the final action (**Stop Failover Group**) is taken because the specified failover count is exceeded through the error detected by Disk monitor resource 1.
- The final action taken by Disk monitor resource 1 on Server 1 causes Failover group A to be stopped. After that, no reaction occurs even if Disk monitor resource 1 detects an error.
- On Server 2, however, manually starting Failover group A causes the final action of Disk monitor resource 1 to be taken, which has not yet been done there.

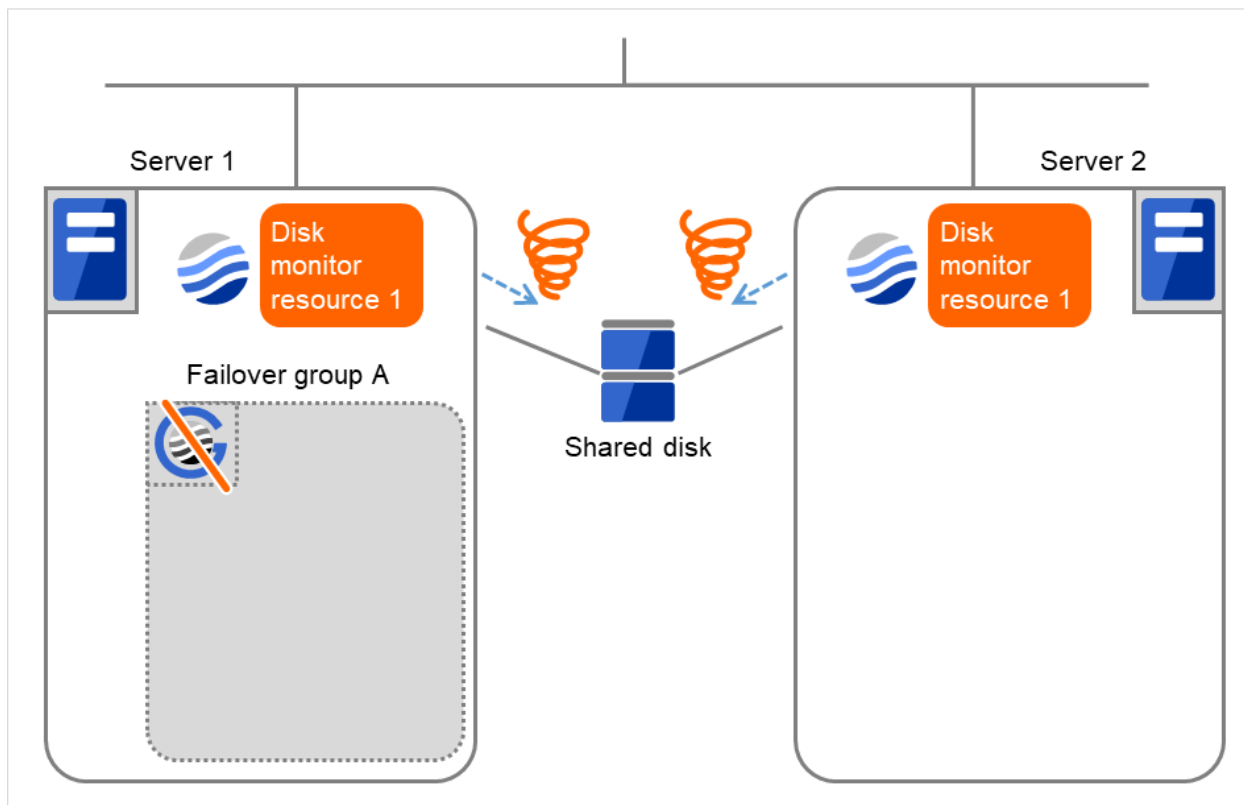

Fig. 4.49: Flow of error detection by the disk monitor resource (12)

	Server 1	Server 2
Disk monitor resource 1 Failover Count	1	1
Disk resource 1 Failover Count	1	1

#### 4.1.9 Recovery/pre-recovery action script

Upon the detection of a monitor resource error, a recovery script can be configured to run. Alternatively, before the reactivation, failover, or final action of a recovery target, a pre-recovery action script can be configured to run.

The script is a common file.

##### Environment variables used in the recovery/pre-recovery action script

EXPRESSCLUSTER sets status information (the recovery action type) in the environment variables upon the execution of the script.

The script allows you to specify the following environment variables as branch conditions according to the operation of the system.

Environment variable	Value of the environment variable	Description
CLP_MONITORNAME ...Monitor resource name	Monitor resource name	Name of the monitor resource in which an error that causes the recovery/pre-recovery action script to run is detected.
CLP_VERSION_FULL ...EXPRESSCLUSTER full version number	EXPRESSCLUSTER full version number	EXPRESSCLUSTER full version number. (Example) 4.3.4-1
CLP_VERSION_MAJOR ...EXPRESSCLUSTER major version	EXPRESSCLUSTER major version	EXPRESSCLUSTER major version (Example) 4
CLP_PATH ...EXPRESSCLUSTER installation path	EXPRESSCLUSTER installation path	Path of EXPRESSCLUSTER installation. (Example) /opt/nec/clusterpro
CLP_OSNAME ...Server OS name	Server OS name	Name of the server OS on which the script is executed. (Example) 1. When the OS name could be acquired: Red Hat Enterprise Linux Server release 6.8 (Santiago) 2. When the OS name could not be acquired: Linux
CLP_OSVER ...Server OS version	Server OS version	Version of the server OS on which the script is executed. (Example) 1. When the OS name could be acquired:6.8 2. When the OS version could not be acquired: *None
CLP_ACTION ...Recovery action type	RECOVERY	Execution as a recovery script.
	RESTART	Execution before reactivation.
	FAILOVER	Execution before failover.
	FINALACTION	Execution before final action.

Continued on next page

Table 4.34 – continued from previous page

Environment variable	Value of the environment variable	Description
CLP_RECOVERYCOUNT ...Recovery script execution count	Recovery Script Execution Count	Count for recovery script execution.
CLP_RESTARTCOUNT ...Reactivation count	Reactivation count	Count for reactivation.
CLP_FAILOVERCOUNT ...Failover count	Failover count	Count for failover.

#### **Writing recovery/pre-recovery action scripts**

This section explains the environment variables mentioned above, using a practical scripting example.

**Example of a recovery/pre-recovery action script**

```
#!/bin/sh

# *****
# *          preactaction.sh
# *****

# Refer to the environment variable of the script execution factor to determine the
↳subsequent process.
if [ "$CLP_ACTION" = "RECOVERY" ]
then
    # Here, write a recovery process.
    # This process is to be performed at the timing of the following:
    #
    # Recovery action: recovery script

elif [ "$CLP_ACTION" = "RESTART" ]
then
    # Here, write a pre-reactivation process.
    # This process is to be performed at the timing of the following:
    #
    # Recovery action: reactivation

elif [ "$CLP_ACTION" = "FAILOVER" ]
then
    # Here, write a recovery process.
    # This process is to be performed at the timing of the following:
    #
    # Recovery action: failover

elif [ "$CLP_ACTION" = "FINALACTION" ]
then
    # Here, write a recovery process.
    # This process is to be performed at the timing of the following:
    #
    # Recovery action: final action

fi
exit 0
```

**Tips for recovery/pre-recovery action script coding**

Pay careful attention to the following points when coding the script.

- When the script contains a command that requires a long time to run, log the end of execution of that command. The logged information can be used to identify the nature of the error if a problem occurs. `clplogcmd` is used to log the information.
- How to use `clplogcmd` in the script  
With `clplogcmd`, messages can be output to Cluster WebUI Alert logs or OS syslog. For `clplogcmd`, see "*Outputting messages (clplogcmd command)*" in "8. EXPRESSCLUSTER command reference" in this guide.

(Ex. : Scripting image)

```
clplogcmd -m "recoverystart.."
recoverystart
clplogcmd -m "OK"
```

#### Note on the recovery/pre-recovery action script

- Stack size for commands and applications activated from the script  
The recovery/pre-recovery action script runs with the stack size configured to 2 MB. If the script has a command or application that requires a stack size of 2 MB or more to run, a stack overflow occurs.  
If a stack overflow error occurs, adjust the stack size before the command or application is activated.
- Condition that a pre-recovery action script is executed as the final action  
A pre-recovery action script is executed as the final action before the final action due to a monitor error detected by a monitor. Even if **No operation** is set as the final action, a pre-recovery action script is executed.  
If the final action is not executed because the maximum restart count has reached the upper limit or by the function to suppress the monitor resource recovery action or the function to suppress the final action when all other servers are being stopped, a pre-recovery action script is not executed.

#### 4.1.10 Delay warning of monitor resources

When a server is heavily loaded, due to a reason such as applications running concurrently, a monitor resource may detect a monitoring timeout. It is possible to have settings to issue an alert at the time when polling time (the actual elapsed time) reaches a certain percentages of the monitoring time before a timeout is detected.

The following figure shows timeline until a delay warning of the monitor resource is used.

In this example, the monitoring timeout is set to 60 seconds and the delay warning rate is set to 80%(48 seconds), which is the default value.

The arrows indicate monitor polling times.

Fig. 4.50: Monitor polling times and a delay warning

- A. The polling time of monitoring is 10 seconds. The target of the monitor resource is in normal status.  
In this case, no alert is used.
- B. The polling time of monitoring is 50 seconds and the delay of monitoring is detected during this time. The target of the monitor resource is in the normal status.  
In this case, an alert is used because the delay warning rate has exceeded 80%.

- C. The polling time of monitoring has exceeded 60 seconds of the monitoring timeout and the delay of monitoring is detected. The target of the monitor resource has a problem.

In this case, no alert is used.

If the delay warning rate is set to 0 or 100:

- When 0 is set to the delay monitoring rate  
An alert for the delay warning is used at every monitoring.  
By using this feature, the polling time for the monitor resource can be calculated at the time the server is heavily loaded, which will allow you to determine the time for monitoring timeout of a monitor resource.
- When 100 is set to the delay monitoring rate  
The delay warning will not be is used.

Alert for the delay warning is used for the heartbeat resources as well.

For the user-mode monitor resource, the same delay monitoring rate as for the monitor resource is used.

---

**Note:** Be sure not to set a low value, such as 0%, except for a test operation.

---

#### 4.1.11 Waiting for monitor resource to start monitoring

"Wait Time to Start Monitoring" refers to start monitoring after the period of time specified as the waiting time elapses.

The following describes how monitoring differs when the wait time to start monitoring is set to 0 second and 30 seconds.

If the wait time to start monitoring is set at 0 seconds, the monitor resource polling is started after a cluster startup or a monitor resumption.

Configuration of monitor resource

<Monitor>

Interval 30 sec

Timeout 60 sec

Retry Count 0 times

Wait Time to Start Monitoring 0 sec

Fig. 4.51: Waiting for monitor resource to start monitoring (with its time set at 0 seconds)

If the wait time to start monitoring is set at 30 seconds, the monitor resource polling is started 30 seconds after a cluster startup or a monitor resumption.

#### Configuration of monitor resource

<Monitor>

Interval 30 sec

Timeout 60 sec

Retry Count 0 times

Wait Time to Start Monitoring 30 sec

Fig. 4.52: Waiting for monitor resource to start monitoring (with its time set at 30 seconds)

---

**Note:** Monitoring will start after the time specified to wait for start monitoring has elapsed even when the monitor resource is suspended and/or resumed by using the monitoring control commands.

---

The wait time to start monitoring is used when there is a possibility for monitoring to be terminated right after the start of monitoring due to incorrect application settings, such as the exec resource monitored by PID monitor resource, and when they cannot be recovered by reactivation.

For example, when the monitor wait time is set to 0 (zero), recovery may be endlessly repeated. See the example below:

In this case, the application is first started. Next, the PID monitor resource starts monitoring, then ends its polling. After that, however, the application abends for some reason.

#### Configuration of PID Monitor resource

<Monitor>

Interval 5 sec

Timeout 60 sec

Retry Count 0 times

Wait Time to Start Monitoring 0 sec

<Error Detection>

Recover Target exec1

Maximum Reactivation Count 1 time

Maximum Failover Count 1 time

Final Action Stop Group

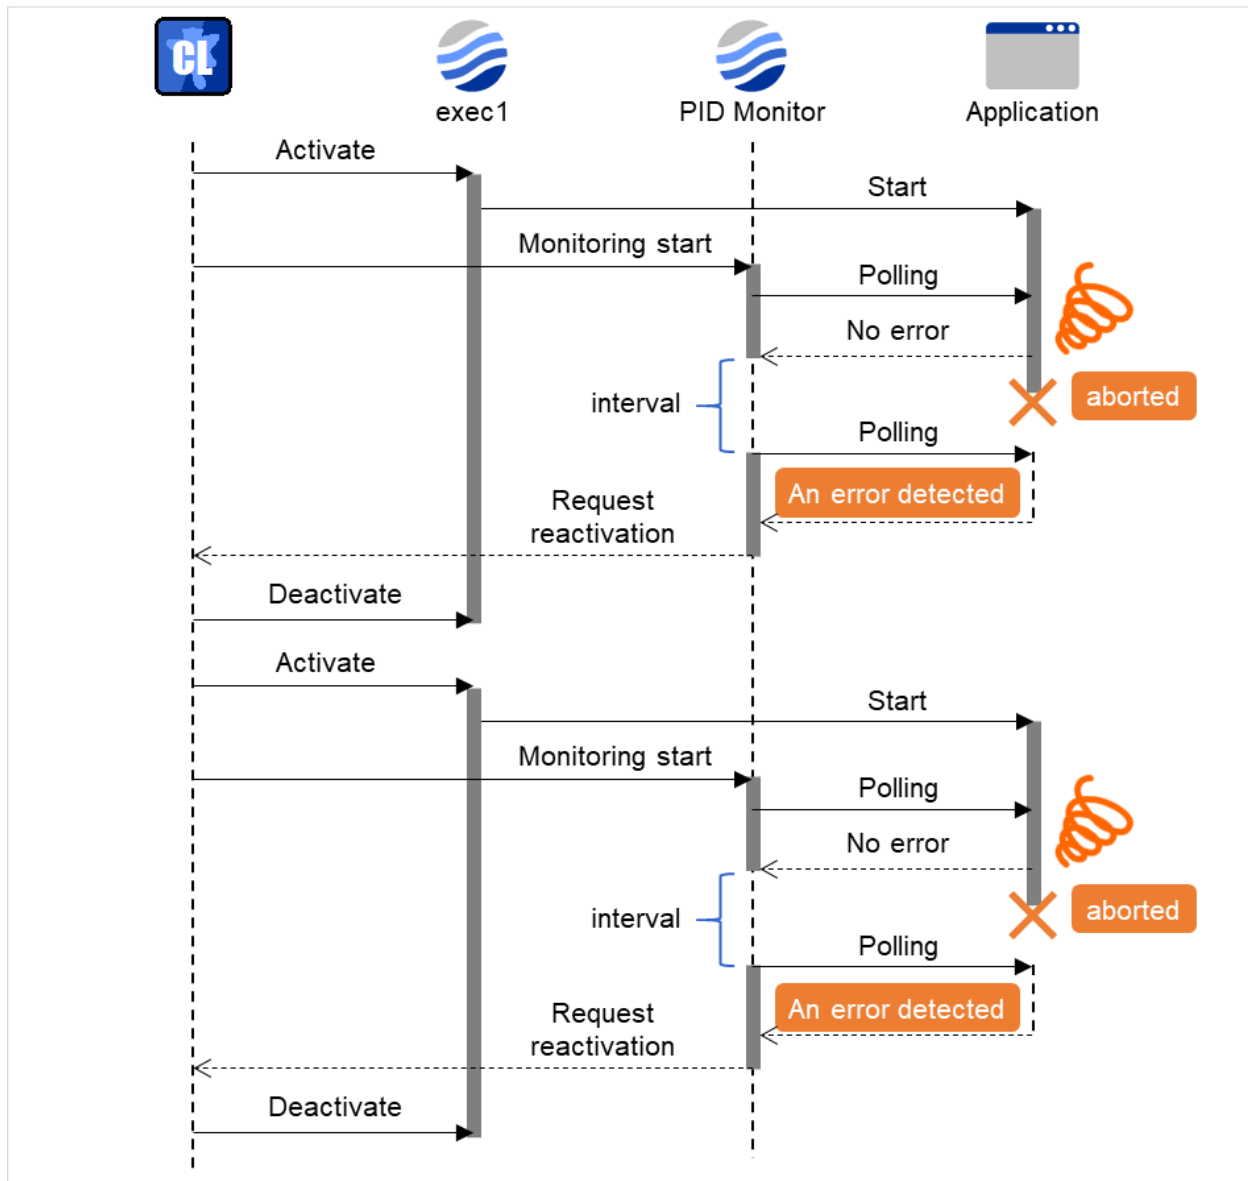

Fig. 4.53: Waiting for monitor resource to start monitoring (with its time set at 0 seconds)

The reason why recovery action is endlessly repeated is because the initial monitor resource polling has terminated successfully. The current count of recoveries the monitor resource has executed is reset when the status of the monitor resource becomes normal (finds no error in the monitor target). Because of this, the current count is always reset to 0 and reactivation for recovery is endlessly repeated.

You can prevent this problem by setting the wait time to start monitoring. By default, 60 seconds is set as the wait time from the application startup to the end.

In this case, the application is first started. Next, through the specified wait time to start monitoring, the PID monitor resource starts monitoring. After that, the application abends for some reason. However, the abend is detected with the first round of polling by the PID monitor resource.

Configuration of PID monitor resource

<Monitor>

Interval 5 sec

Timeout 60 sec

Retry Count 0 times

Wait Time to Start Monitoring 60 sec

<Error Detection>

Recover Target exec1

Maximum Reactivation Count 1 time

Maximum Failover Count 1 time

Final Action Stop Group

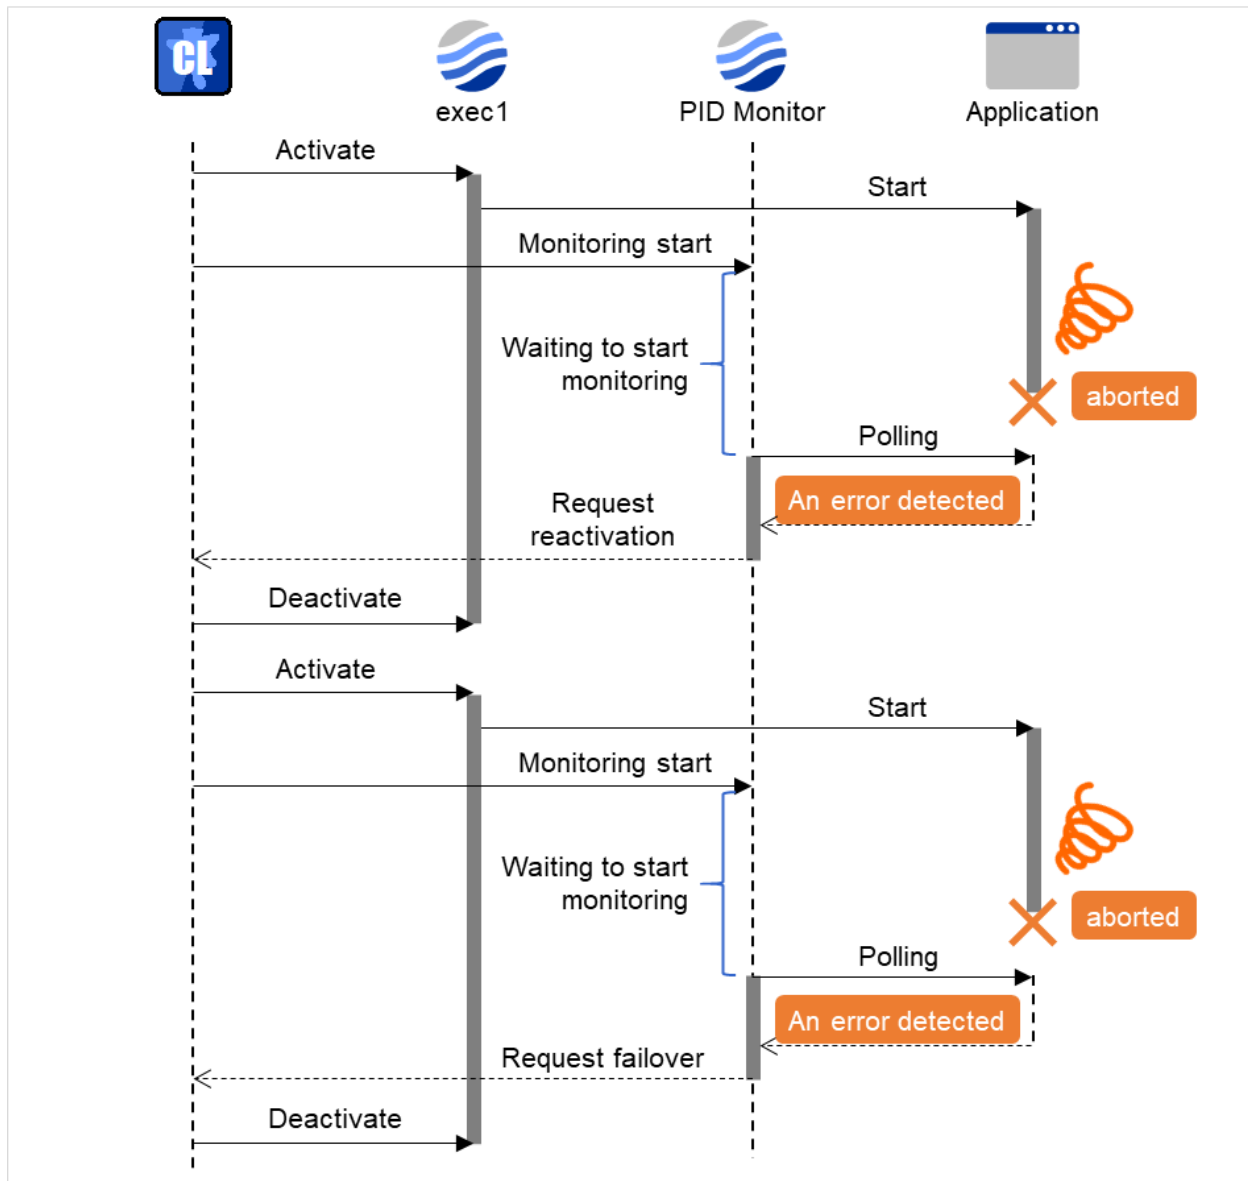

Fig. 4.54: Waiting for monitor resource to start monitoring (with its time set at 60 seconds)

If the application is abnormally terminated in the destination server of the group failover, the group stops as the final action.

### 4.1.12 Limiting the number of reboots when an error is detected by the monitor resource

When **Stop cluster service and shutdown OS** or **Stop cluster service and reboot OS** is selected as a final action to be taken when an error is detected by the monitor resource, the number of shutdowns or reboots can be limited.

---

**Note:**

The maximum reboot count is on a server basis because the number of reboots is recorded on a server basis.

The number of reboots caused by a final action in detection of error in group activation/deactivation and the number of reboots caused by a final action in detection of error by a monitor resource are recorded separately.

If the time to reset the maximum reboot count is set to zero (0), the number of reboots will not be reset.

---

The following is an example of the process when the number of reboots is limited.

As a final action, **Stop cluster daemon and reboot OS** is executed once because the maximum reboot count is set to one (1).

When the monitor resource finds no error in its target for 10 minutes after reboot following cluster shutdown, the number of reboots is reset because the time to reset the maximum reboot count is set to 10 minutes.

Examples of behavior when the following values are set.

Configuration

<Monitor>

Interval 60 sec

Timeout 120 sec

Retry Count 3 times

<Error detection>

Recovery Target Failover Group A

Maximum Reactivation Count 0 times

Maximum Failover Count 0 times

Final Action **Stop cluster daemon and reboot OS**

<Reboot count limit >

Maximum reboot count 1 time

Time to reset the maximum reboot count 10 minutes

(1) The following figure shows an example of monitoring by the disk monitor resource on two servers.

Disk monitor resource 1 starts to be activated. At the intervals, an I/O process or other processes are executed on the device.

Fig. 4.55: Limiting the number of reboots (1)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	0	0

(2) Disk monitor resource 1 detects an error (e.g. that of ioctl or read).

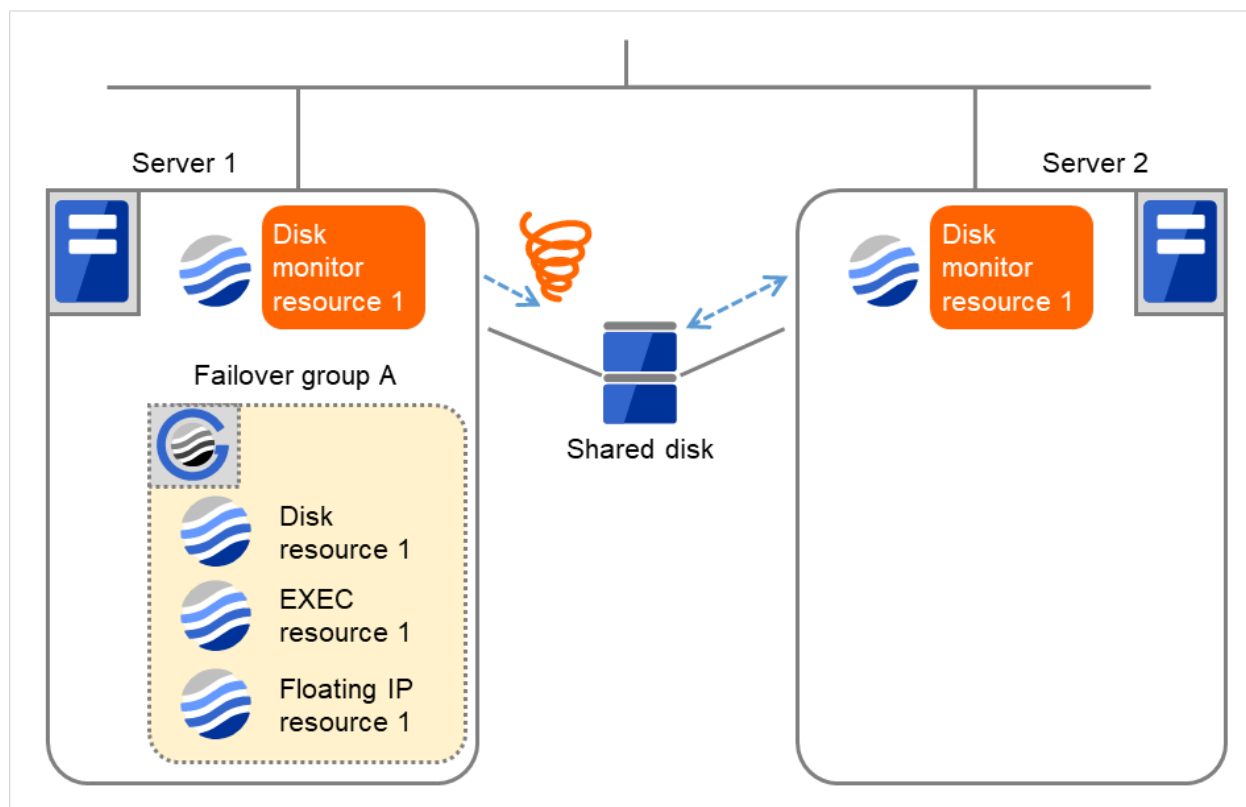

Fig. 4.56: Limiting the number of reboots (2)

- (3) Stop the cluster service, and then reboot the OS.

Since both **Retry Count at Activation Failure** and **Failover Threshold** are set at zero (0), the final action is taken.

The number of reboots is recorded as 1.

Then Failover group A starts to be failed over.

**Maximum reboot count** represents the upper limit of how many times the startup is done on each server.

On Server 2, the number of reboots is zero (0).

Fig. 4.57: Limiting the number of reboots (3)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(4) Server 1 completes the reboot.

Move Failover group A to Server 1 by using the `clpgrp` command or Cluster WebUI.

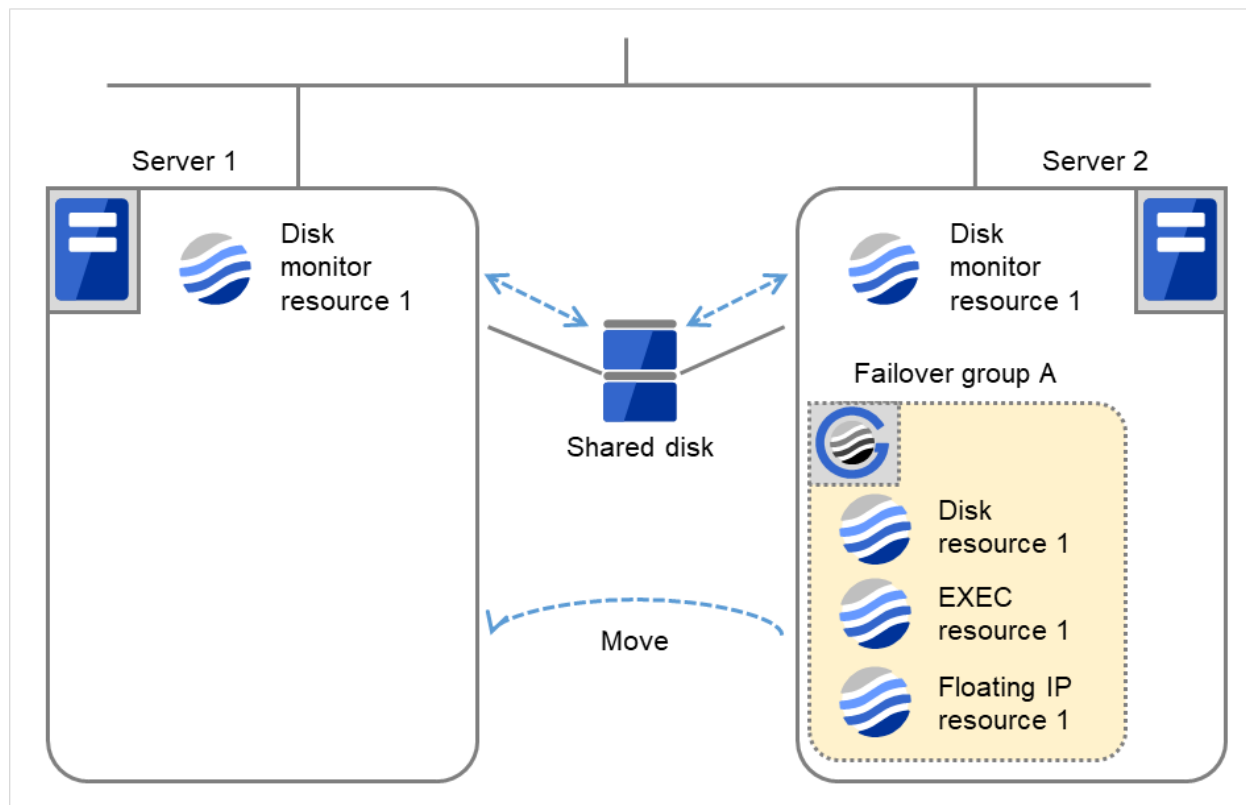

Fig. 4.58: Limiting the number of reboots (4)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

(5) Disk monitor resource 1 detects an error (e.g. that of `ioctl` or `read`).

The final action is not taken on Server 1, because the reboot count has reached its maximum.

Even after 10 minutes pass, the reboot count is not reset.

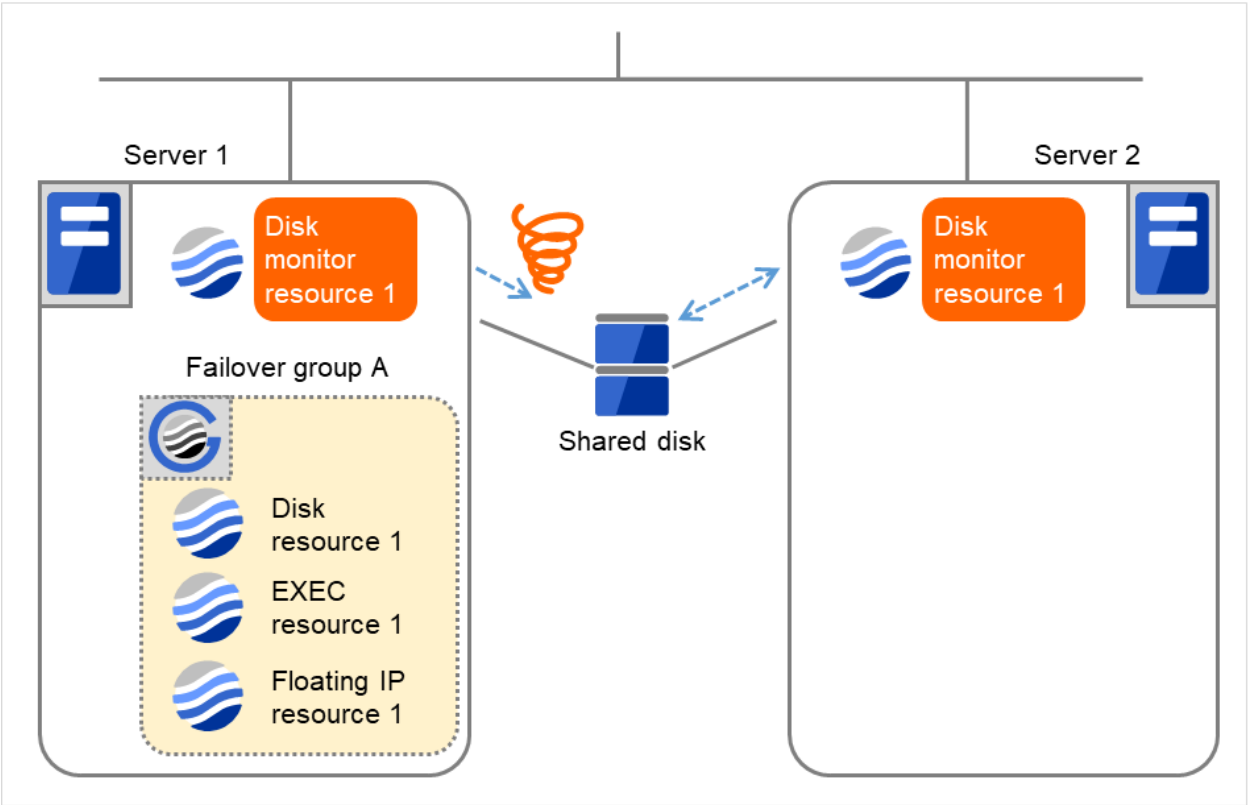

Fig. 4.59: Limiting the number of reboots (5)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

- (6) Remove the error from the shared disk, shut down the cluster by using the `clpstdn` command or Cluster WebUI, and then start the reboot.

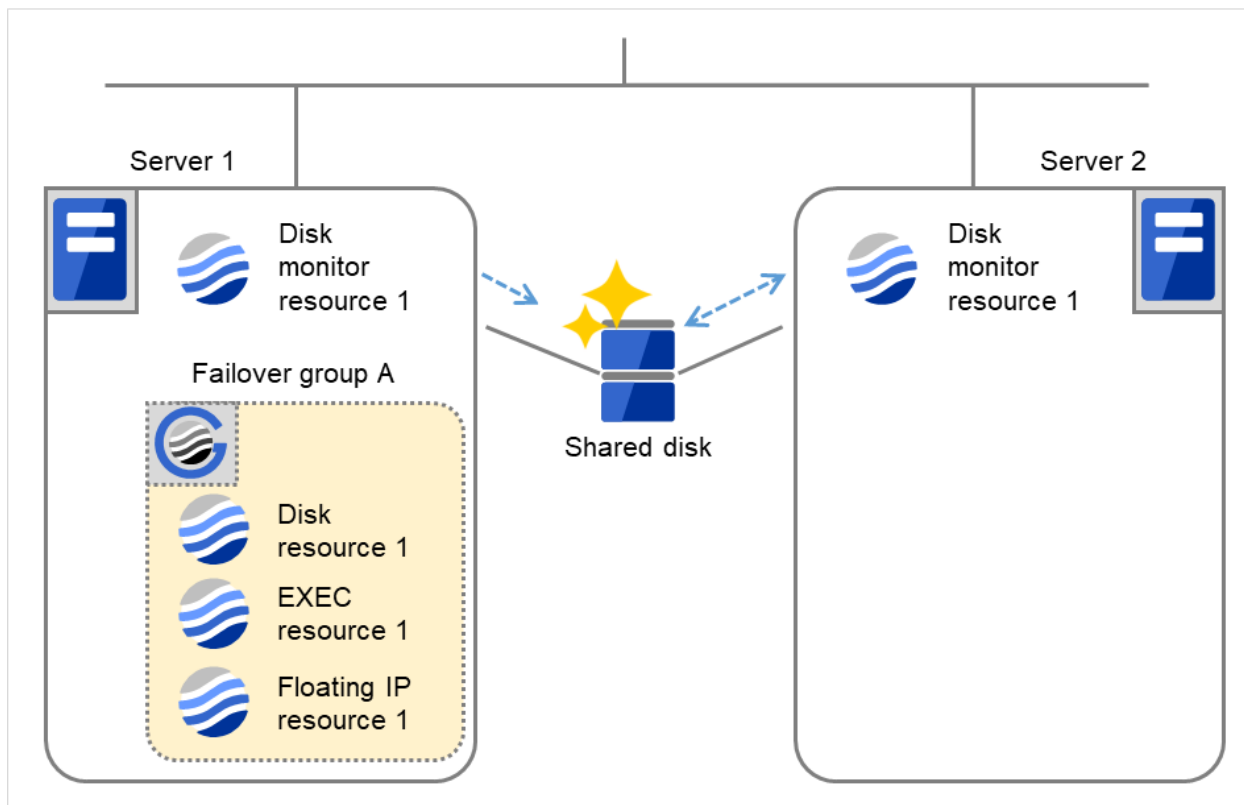

Fig. 4.60: Limiting the number of reboots (6)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	1	0

- (7) On Server 1, Disk monitor resource 1 returns to normal.  
After 10 minutes pass, the reboot count is reset.  
Next time Disk monitor resource 1 detects an error, the final action is taken.

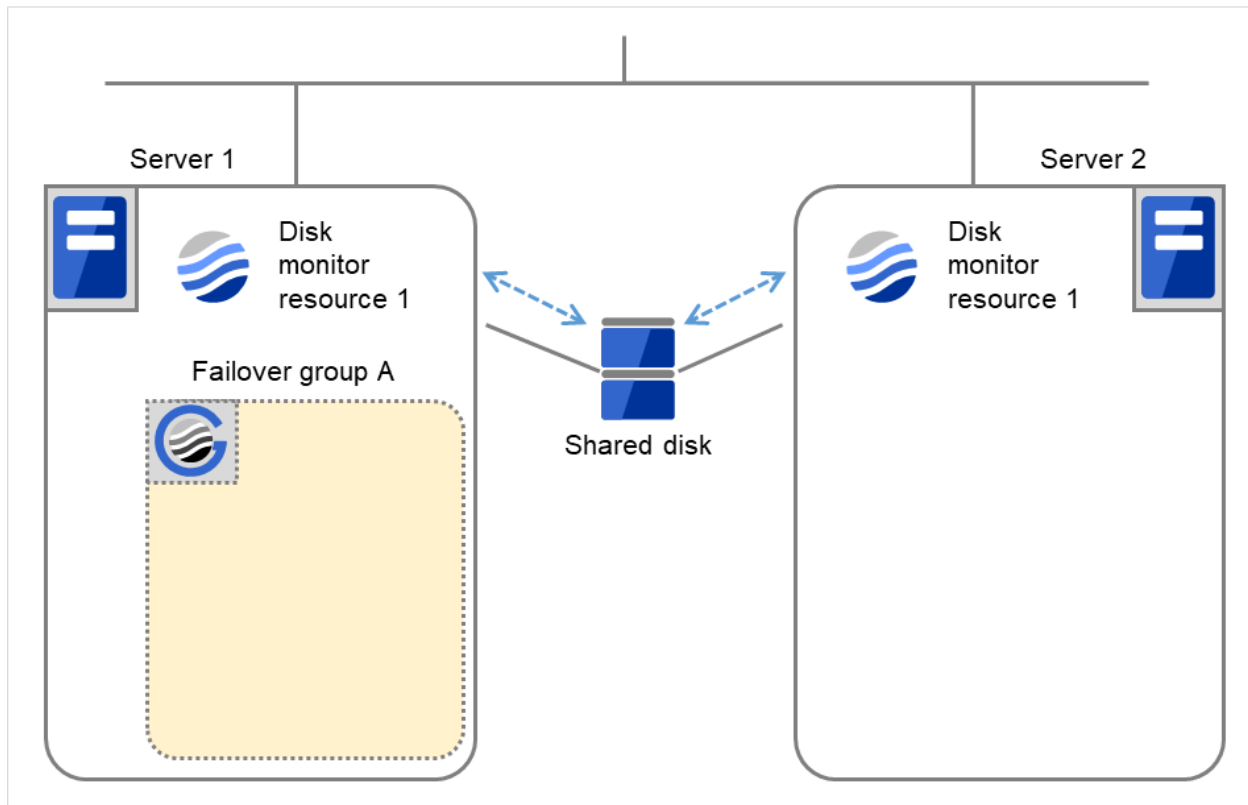

Fig. 4.61: Limiting the number of reboots (7)

	Server 1	Server 2
Maximum reboot count	1	1
Reboot count	0	0

### 4.1.13 Monitor priority of the monitor resources

To assign a higher priority for monitor resources to monitor when the operating system is heavily loaded, the nice value can be set.

- The nice value can be specified through minus 19 (low priority) to plus 20 (high priority). Detection of the monitor timeout can be controlled by setting a higher priority to the nice value.

#### 4.1.14 IPMI command

Final actions **BMC Reset**, **BMC Power Off**, **BMC Power Cycle**, and **BMC NMI** use the ipmitool command.

If the commands are not installed, this function cannot be used.

##### Notes for the final action by ipmi

- Final Action by IPMI is achieved by associating EXPRESSCLUSTER and the ipmitool command.
- ipmitool(OpenIPMI-tools) is not shipped with EXPRESSCLUSTER. Users are required to install the rpm package by themselves.
- When executing the final action by the ipmitool command, the ipmi driver needs to be loaded. It is recommended to load the ipmi driver automatically at OS startup.

Chassis identify uses the ipmitool command.

If the commands are not installed, this function cannot be used.

##### Notes for chassis identify by ipmi

Chassis identify by ipmi is actualized by combining EXPRESSCLUSTER and the ipmitool command.

ipmitool(OpenIPMI-tools) is not shipped with EXPRESSCLUSTER. Users are required to install the rpm package by themselves.

#### 4.1.15 Setting monitor resources on individual servers

Some setting values of monitor resources can be set for individual servers. For the resources which can be configured on a server basis, the tabs of servers are displayed on the **Monitor(special)** tab.

The following monitor resources can be configured for individual servers.

Monitor resource name	Supported version
Disk monitor resource	4.0.0-1 or later
IP monitor resource	4.0.0-1 or later
NIC Link Up/Down monitor resource	4.0.0-1 or later
Message receive monitor resource	4.0.0-1 or later
AWS Elastic IP monitor resource	4.0.0-1 or later
AWS Virtual IP monitor resource	4.0.0-1 or later
AWS AZ monitor resource	4.0.0-1 or later
AWS DNS monitor resource	4.0.0-1 or later

For the parameters that can be configured for individual servers, see the descriptions of parameters on monitor resources. These parameters are marked with "Server Individual Setup".

In the example below, configuring settings for each server on the disk monitor resource is described.

Monitor Resource Properties | diskw1 diskw ✕

Info Monitor(common) Monitor(special) Recovery Action

Common server1 server2

Method\* READ(O\_DIRECT) ▾

Monitor Target\* /dev/sdb2 ▾

Monitor Target RAW Device Name

I/O size 2000000 byte

Action When Diskfull Is Detected Recover ▾

OK Cancel Apply

### Server Individual Setup

Parameters that can be configured for individual servers on a disk monitor resource are displayed.

Monitor Resource Properties | diskw1 diskw ✕

Info Monitor(common) Monitor(special) Recovery Action

Common server1 server2

Set Up Individually ☒

Method\* READ(O\_DIRECT) ▾

Monitor Target\* /dev/sdb2 ▾

Monitor Target RAW Device Name

I/O size 2000000 byte

Action When Diskfull Is Detected Recover ▾

OK Cancel Apply

### Set Up Individually

Click the tab of the server on which you want to configure server individual setting, and select this check box. The boxes for parameters that can be configured for individual servers become active. Enter required parameters.

## 4.1.16 Common settings for monitor resources of the monitoring option

This section describes the setting procedure for, and cautions related to, monitoring applications by using the monitor resources provided by the Application Server Agent, Database Agent, File Server Agent, Internet Server Agent, Java Resource Agent, and System Resource Agent (hereinafter referred to as "monitoring option").

### Setting procedure of monitor resources of monitoring option

Follow the steps below to monitor applications by using monitor resources of the monitoring options.

In this example, DB2 monitor resource is used.

1. Create a failover group (for target monitoring application)

2. Add the EXEC resource for target monitoring application startup
3. Perform the test for target monitoring application startup
4. Add DB2 monitor resource for monitoring target monitoring application

The steps are described below.

#### **Step 1 Create a failover group (for target monitoring application)**

Create a failover group for monitoring the target monitoring application and performing a failover when an error occurs. Add group resources as necessary.

---

**Note:** For details on how to create failover groups and add group resources, see "Creating the cluster configuration data" in the "Installation and Configuration Guide".

---

#### **Step 2 Add the EXEC resource for starting the target monitoring application**

Add the EXEC resource for starting the target monitoring application to the failover group that you have created in Step 1, and edit it to start and finish the target monitoring application by its Start Script or Stop Script. In this guide, this EXEC resource is called `exec 1`.

#### **Step 3 Confirmation test for target monitoring application startup**

After completing the Steps 1 and 2, check that the monitored application is started normally. Modify the settings to the server, start, stop, move and fail over the group by the Cluster WebUI and confirm that those operations are performed normally.

#### **Step 4 Add the DB2 monitor resource for starting target monitoring application**

Add the DB2 monitor resource for monitoring the target monitoring application.

Select **Active** for **Monitor Timing** and specify `exec1` for **Target Resource** on the **Monitor (common)** tab.

---

**Note:** For specific information on the monitor resources and settings, see the section on monitoring option monitor resources in "*Monitor resource details*" in this guide.

---

#### **See also:**

For details on the monitoring settings common to monitor resources, see "*Monitor (common) tab*"

## 4.2 Monitor Common Properties

Monitor Common Properties

Name	Type	Interval	Timeout	Retry Count	Monitor Timing	Ti
<a href="#">fipw1</a>	Floating IP monitor	60 sec	180 sec	1 time	Active	fip
<a href="#">userw</a>	User mode monitor	3 sec	90 sec	0 time	Always	-

<

>

Close

Displays a list of monitor resources.

Clicking a name link takes you to the property screen of the corresponding monitor resource.

## 4.3 Monitor resource properties

### 4.3.1 Info tab

The screenshot shows the 'Monitor Resource Properties' dialog box for resource 'fipw1'. The 'Info' tab is selected. It contains fields for 'Name' (fipw1) and 'Comment'. At the bottom are 'OK', 'Cancel', and 'Apply' buttons.

#### Name

The monitor resource name is displayed.

#### Comment (within 127 bytes)

Enter a comment for the monitor resource. Use only one-byte alphabets and numbers.

### 4.3.2 Monitor (common) tab

The screenshot shows the 'Monitor Resource Properties' dialog box for resource 'fipw1', with the 'Monitor(common)' tab selected. It contains various configuration options:

- Interval\***: 60 sec
- Timeout\***: 180 sec
- Collect the dump file of the monitor process at timeout occurrence**: ☐
- Do Not Retry at Timeout Occurrence**: ☒
- Action at Timeout Occurrence**: Do not recover (dropdown)
- Retry Count\***: 1 time
- Wait Time to Start Monitoring\***: 0 sec
- Monitor Timing**:
  - ☐ Always
  - ☒ Active
- Target Resource\***: fip (with a 'Browse' button)
- Nice Value**: A slider set to 0 (with a text input field showing 0)
- Choose servers that execute monitoring**: Server (dropdown)
- Send polling time metrics**: ☐

At the bottom are 'OK', 'Cancel', and 'Apply' buttons.

**Interval(1 to 999)**

Specify the interval to check the status of monitor target.

**Timeout(5 to 999<sup>5</sup>)**

When the normal status cannot be detected within the time specified here, the status is determined to be error.

**Collect the dump file of the monitor process at timeout occurrence**

In case that this function is enabled, the dump information of the timed out monitor resource is collected when the monitor resource times out. The collected dump information is written to the /opt/nec/clusterpro/work/rm/"monitor\_resource\_name"/errinfo.cur folder. When dump is performed more than once, the existing folders are renamed errinfo.1, errinfo.2, and so on. Dump information is collected up to 5 times.

**Do Not Retry at Timeout Occurrence**

When this function is enabled, recovery action is executed immediately if a monitor resource timeout occurs.

**Do Not Execute Recovery Action at Timeout Occurrence**

When this function is enabled, recovery action is not executed if a monitor resource timeout occurs.

This can be set only when the Do Not Retry at Timeout Occurrence function is enabled.

---

**Note:** For the following monitor resources, the Do Not Retry at Timeout Occurrence and Do Not Execute Recovery Action at Timeout Occurrence functions cannot be set.

- User mode monitor resource
- Multi target monitor resource
- Virtual IP monitor resource
- Custom monitor resource (only when Monitor Type is **Asynchronous**)
- Message receive monitor resource
- VM monitor resource
- Dynamic DNS monitor resource
- BMC monitor resource
- Oracle Clusterware Synchronization Management monitor resource
- JVM monitor resource
- System monitor resource
- Process resource monitor resource

---

**Retry Count(0 to 999)**

Specify how many times an error should be detected in a row after the first one is detected before the status is determined as error. If this is set to zero (0), the status is determined as error at the first detection of an error.

**Wait Time to Start Monitoring(0 to 9999)**

Set the wait time to start monitoring.

---

<sup>5</sup> When ipmi is set as a monitoring method for the user-mode monitor resource, 255 or less should be specified.

### Monitor Timing

Set the monitoring timing. Select the timing from:

- Always:  
Monitoring is performed all the time.
- Active:  
Monitoring is not started until the specified resource is activated.

### Target Resource

The resource which will be monitored when activated is shown.

### Browse

Click this button to open the dialog box to select the target resource. The group names and resource names that are registered in the LocalServer and cluster are shown in a tree view. Select the target resource and click **OK**.

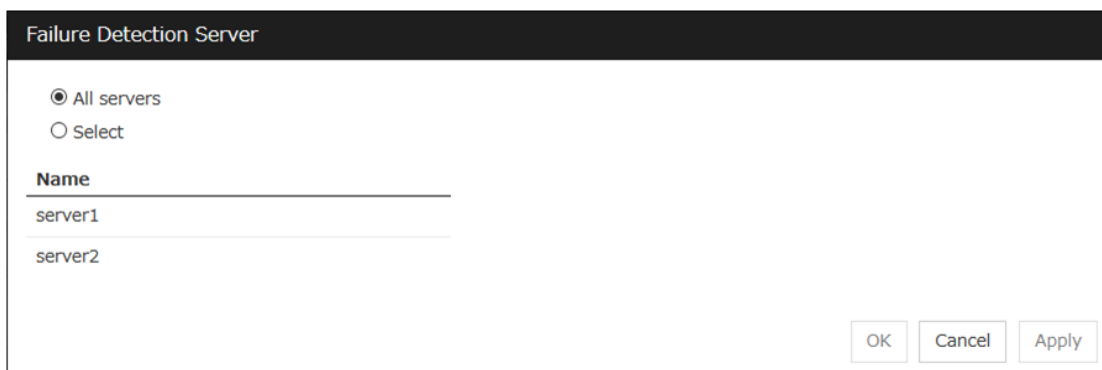

### Nice Value

Set the nice value of a process.

### Choose servers that execute monitoring

Choose the servers that execute monitoring.

### All Servers

All servers monitor the resources.

### Select

Servers registered in **Available Servers** monitor the resources. One or more servers need to be set to **Available Servers**.

- Add

Click this button to add a server selected in Available Servers to Servers that can run the Group.

- **Remove**

Delete a server selected from Servers that can run the Group.

### Send polling time metrics

Enable or disable sending metrics: data on the monitoring process time taken by the monitor resource.

- If the check box is checked:  
The metrics are sent.
- If the check box is not checked:  
The metrics are not sent.

---

### Note:

For using the Amazon CloudWatch linkage function, enabling this option allows you to send data on the monitoring process time taken by any monitor resource.

**Send polling time metrics** cannot be set for the following monitor resources:

- User mode monitor resources
  - custom monitor resources (only when Monitor Type is **Asynchronous**)
  - Virtual IP monitor resource
  - Message receive monitor resource
  - VM monitor resource
  - Dynamic DNS monitor resource
  - BMC monitor resource
  - Oracle Clusterware Synchronization Management monitor resource
  - JVM monitor resource
  - System monitor resource
  - Process resource monitor resource
- 

## 4.3.3 Monitor (special) tab

Some monitor resources require the parameters at the monitoring operation to be configured. The parameters are described in the explanation part about each resource.

## 4.3.4 Recovery Action tab

In this dialog box, the recovery target and an action to be taken at the time when an error is detected can be configured. By setting this, it allows failover of the group, restart of the resource and cluster when an error is detected. However, recovery will not occur if the recovery target is not activated.

## Recovery Action

Select a recovery action when detecting an error.

- Executing failover the recovery target  
When detecting a monitor error, execute failover to the group to which the groups or group resources selected as the recovery target belong.
- Restart the recovery target, and if there is no effect with restart, then failover  
Reactivate groups or group resources selected as the recovery target. If the reactivation fails, or the same error is detected after the reactivation, then execute failover.
- Restart the recovery target  
Reactivate the selected group or group resource as the recovery target.
- Execute only the final action  
Execute the selected action as the final action.
- Custom settings  
Execute the recovery script up until the maximum script execution count. If an error is continuously detected after script execution, reactivate the selected group or group resource as the recovery target up until the maximum reactivation count. If reactivation fails or the same error is continuously detected after reactivation, and the count reaches the maximum reactivation count, execute failover for the selected group or group resource as the recovery target, up until the maximum failover count. When failover fails or the same error is continuously detected after failover, and the count

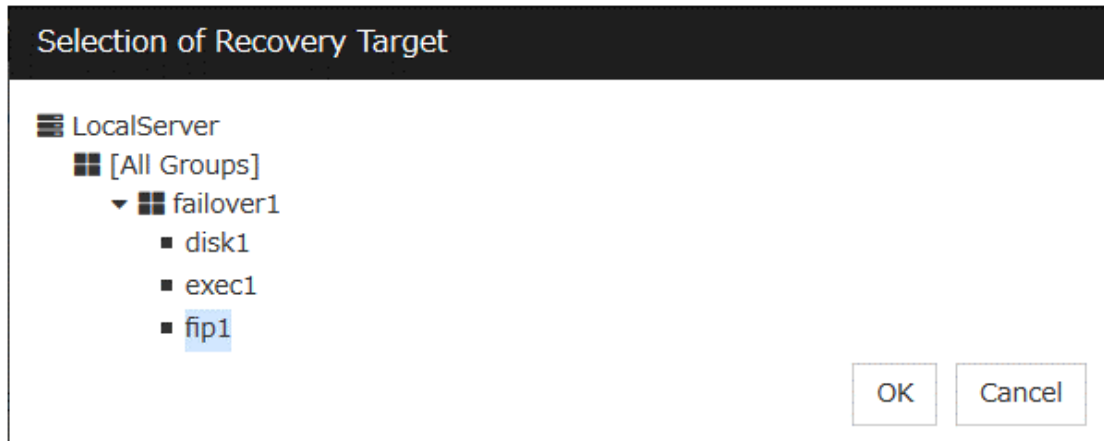

reaches the maximum failover count, execute the selected action as the final action.

### Recovery Target

A target is shown, which is to be recovered when it is determined as a resource error.

#### Browse

Click this button to open the dialog box in which the target resource can be selected. The LocalServer, All Groups and group names and resource names that are registered in the cluster are shown in a tree view. Select the target resource and click **OK**.

#### Recovery Script Execution Count (0 to 99)

Specify the number of times to allow execution of the script configured by **Script Settings** when an error is detected. If this is set to zero (0), the script does not run.

#### Execute Script before Reactivation

- When the check box is selected:  
A script/command is executed before reactivation. To configure the script/command setting, click **Script Settings**.
- When the check box is not selected:  
Any script/command is not executed.

#### Maximum Reactivation Count(0 to 99)

Specify how many times you allow reactivation when an error is detected. If this is set to zero (0), no reactivation is executed. This is enabled when a group or group resource is selected as a recovery target.

When the group to which dynamic failover or a resource which belongs to that group is set as a recovery target of an IP monitor resource or NIC Link Up/Down monitor resource, reactivating the recovery target fails because a monitor resource registered in the exception list detects an error.

#### Execute Script before Failover

- When the check box is selected:  
A script/command is executed before failover. To configure the script/command setting, click **Script Settings**.
- When the check box is not selected:  
Any script/command is not executed.

#### Execute migration before Fail over

When the check box is selected, execute migration before executing failover at error detection.

### Maximum Failover Count(0 to 99)

Specify how many times you allow failover after reactivation fails for the number of times set in **Maximum Reactivation Count** when an error is detected. If this is set to zero (0), no failover is executed. This can be settable when selecting "All Groups", a group or a group resource as the recovery target. When "All Groups" is selected, execute failover of all groups running on the server of which the monitor resource has detected errors.

### Execute Script before Final Action

Select whether script is run or not before executing final action.

- When the check box is selected:  
A script/command is run before executing final action. To configure the script/command setting, click **Script Settings**.
- When the check box is not selected:  
Any script/command is not run.

When clicking **Script Settings** of **Execute Script before Final Action**, **Edit Script** dialogbox is displayed. Set script or script file, and click OK.

### Script Settings

Click here to display the **Edit Script** dialog box. Configure the recovery or pre-recovery action script or commands.

### User Application

Use an executable file (executable shell script file or execution file) on the server as a script. For the file name, specify an absolute path or name of the executable file of the local disk on the server. If there is any blank in the absolute path or the file name, put them in double quotation marks (") as follows.

Example:

`"tmp/user application/script.sh"`

Each executable file is not included in the cluster configuration information of the Cluster WebUI. They must be prepared on each server because they cannot be edited or uploaded by the Cluster WebUI.

### Script created with this product

Use a script file which is prepared by the Cluster WebUI as a script. You can edit the script file with the Cluster WebUI if you need. The script file is included in the cluster configuration information.

**File**(Within 1023 bytes)

Specify a script to be executed (executable shell script file or execution file) when you select **User Application**.

**View**

Click here to display the script file when you select **Script created with this product**.

**Edit**

Click here to edit the script file when you select **Script created with this product**. Click **Save** the script file to apply the change. You cannot modify the name of the script file.

**Replace**

Click here to replace the contents of a script file with the contents of the script file which you selected in the **file selection** dialog box when you select **Script created with this product**. You cannot replace the script file if it is currently displayed or edited. Select a script file only. Do not select binary files (applications), and so on.

**Timeout** (1 to 9999)

Specify the maximum time to wait for completion of script to be executed. The default value is set as 5.

**Final Action**

Select a final action to be taken after reactivation fails for the number of times set in **Maximum Reactivation Count**, and failover fails for the number of times set in **Maximum Failover Count** when an error is detected.

Select the final action from the options below:

- No Operation  
No action is taken.

---

**Note:** Select **No Operation** only when (1) temporarily canceling the final action, (2) displaying only an alert when an error is detected, and (3) executing the final action by multi target monitor resource.

---

- Stop Resource  
When a group resource is selected as a recovery target, the selected group resource and group resources that depend on the selected group resource are stopped.  
This option is disabled when "LocalServer", "All Groups", or a group is selected.
- Stop Group  
When a group is selected as a recovery target, that group is stopped. When a group resource is selected as a recovery target, the group that the group resource belongs is stopped. When "All Groups" is selected, stop all the groups running on the server of which the monitor resource has detected errors.  
This option is disabled when "LocalServer" is selected as the recovery target.
- Stop cluster service  
Stops the cluster service of the server that detected an error.
- Stop cluster service and shutdown OS  
Stops the cluster service of the server that detected an error, and then shuts down the OS.

- Stop cluster service and reboot OS  
Stops the cluster service of the server that detected an error, and then reboots the OS.
- Generate intentionally stop error  
Generate stop error intentionally to the server.
- Sysrq Panic  
Performs the sysrq panic.

---

**Note:** If performing the sysrq panic fails, the OS is shut down.

---

- Keepalive Reset  
Resets the OS using the clpkhb or clpka driver.

---

**Note:** If resetting keepalive fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported.

---

- Keepalive Panic  
Performs the OS panic using the clpkhb or clpka driver.

---

**Note:** If performing the keepalive panic fails, the OS is shut down. Do not select this action on the OS and kernel where the clpkhb and clpka drivers are not supported.

---

- BMC Reset  
Perform hardware reset on the server by using the ipmi command.

---

**Note:** If resetting BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC Power Off  
Powers off the OS by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If powering off BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC Power Cycle  
Performs the power cycle (powering on/off) of the server by using the ipmi command. OS shutdown may be performed due to the ACPI settings of the OS.

---

**Note:** If performing the power cycle of BMC fails, the OS is shut down. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- BMC NMI  
Uses the ipmi command to cause NMI occur on the server. Actions after NMI occurrence depend on the OS settings.

---

**Note:** If BMC NMI fails, the OS shutdown is performed. Do not select this action on the server where OpenIPMI is not installed, or the ipmitool command does not run.

---

- I/O Fencing(High-End Server Option)  
It can't be used.

---

**Note:** If I/O Fencing(High-End Server Option) fails, the OS shutdown is performed.

---

### Collect Dump at Timeout

Select whether to enable this function.

Length: Within 4 bytes

Default value: 0 (disabled)

## 4.4 Understanding the disk monitor resources

Disk monitor resources monitor disk devices.

It is recommended to use the READ (O\_DIRECT) monitoring method for disks where disk monitor resources cannot be used (TUR method).

### 4.4.1 Monitoring by disk monitor resources

Two ways of monitoring are employed by the disk monitor resource: READ and TUR.

- Notes on TUR:
  - You cannot run the Test Unit Ready and the SG\_IO command of SCSI on a disk or disk interface (HBA) that does not support it. Even if your hardware supports this command, consult the driver specifications because the driver may not support it.
  - ioctl may be incorrectly executed for an LVM logical volume (LV) device. Use READ for LV monitoring.
  - A TUR method cannot be used for the IDE interface disk.
  - In the case of the disk of S-ATA interface, it may be recognized as the IDE interface disk (hd) or as the SCSI interface disk (sd) depending on the type of a disk controller and the distribution to be used. When the disk is recognized as the IDE interface, no TUR methods can be used. If the disk is recognized as the SCSI interface, TUR (generic) cannot be used but TUR (legacy) can be used.
  - Test Unit Ready, compared to Read, burdens OS and disks less.
  - In some cases, Test Unit Ready may not be able to detect actual errors in I/O to media.
  - You cannot use a partition on the disk by setting it as the target to be monitored. A whole device (whole disk) must be specified.
  - Some disk devices may temporarily return Unit Attention at TUR issue, depending on the device status. The temporary return of Unit Attention does not signify a problem. If the TUR retry count is set to 0, however, the above return is determined to be an error and the disk monitor resource becomes abnormal. To avoid this meaningless error detection, set the retry count to one or more.

For the TUR monitoring, one of the following is selected:

- TUR
  - ioctl is used by the following steps and the status of the device is determined by the result of the command:  
Run the ioctl (SG\_GET\_VERSION\_NUM) command. The status is determined by the return value of ioctl and the version of SG driver.  
If the ioctl command runs successfully and the version of SG driver is 3.0 or later, execute ioctl TUR (SG\_IO) using the SG driver.  
If the ioctl command fails or the version of SG driver is earlier than 3.0, execute ioctl TUR which is defined as a SCSI command.
- TUR (legacy)
  - Monitoring is performed by using ioctl (Test Unit Ready). Test Unit Ready (TUR) which is defined as a SCSI command is used against the specified device, and the status of the device is determined by the result of the command.
- TUR (generic)

- Monitoring is executed by using ioctl TUR (SG\_IO). ioctl TUR (SG\_IO) which is defined as a SCSI command is used against the specified device, and the status of the device is determined by the result of the command. Even with a SCSI disk, SG\_IO may not work successfully depending on the OS or distribution.

The following is the READ monitoring:

- READ
  - The specified size of the specified device (disk device or partition device) or file is read. Judgment is performed by the size that could be read.
  - Dummy Read is for determining if the specified size of data can be read. Validity of the data read is not judged.
  - Burden of the load experienced by the OS and disk is proportional to the size of the data on the specified disk to be read
  - See *"I/O size when READ is selected for disk monitor resources"* to configure the read size.

The following is the READ (O\_DIRECT) monitoring:

- READ (O\_DIRECT)
  - A single sector on the specified device (disk device or partition device) or the file are read without using the cache (O\_DIRECT mode), and the results are (the size of the data successfully read) are used to make a judgment.
  - Judgment is based on whether or not reading has been performed successfully. Validity of the read data is not judged.

The following describes READ (raw) monitoring:

- READ (raw)
  - Like the READ (O\_DIRECT) monitoring method, the process to read the specified device is monitored without using the OS cache.
  - Whether reading was successful is checked. The validity of read data is not checked.
  - When the READ (raw) monitoring method is specified, partitions that have been or will possibly be mounted cannot be monitored. In addition, a whole device (whole disk) that includes partitions that have been or will possibly be mounted cannot be monitored. Allocate a partition dedicated to monitoring and specify it as the disk monitor resource. (Allocate 10 MB or more to the monitoring partition).
  - Do not register a raw device that is already registered in the **Disk I/F** list or **Disk Resource** under the server properties. For details on the VxVM volume raw device, see "Notes when creating EXPRESSCLUSTER configuration data" , "Verifying raw device for VxVM" in "Notes and Restrictions" of the "Getting Started Guide".
  - When monitoring the raw device used by the disk heartbeat by using the READ (raw) monitoring method, specify the raw device for **Monitor Target Raw Device Name in Cluster WebUI. Do not fill in Device Name.**

The following describes READ (VXVM) monitoring:

- READ (VXVM)
  - Like the READ (O\_DIRECT) monitoring method, the process to read the specified device is monitored without using the OS cache.
  - Whether reading was successful is checked. The validity of read data is not checked.
  - The READ (VXVM) monitoring method can be used only when the file system of the volume raw device is vxfs.

The following is the WRITE (FILE) monitoring:

- WRITE (FILE)
  - The file of the specified path is created, written, and deleted to be judged. Validity of the written data is not judged.

#### **4.4.2 I/O size when READ is selected for disk monitor resources**

Enter the size of data when READ is selected as a method of monitoring.

Depending on the shared disk and interfaces in your environment, various caches for reading may be implemented. Because of this, when the specified read size is too small, READ may hit in cache, and may not be able to detect read errors.

When you specify a READ I/O size, verify that READ can detect I/O errors on the disk with that size by intentionally creating I/O errors.

The following figure shows an example of two servers and a shared disk connected to them.

A cache exists in the interface adapter (HBA for SCSI, Fibre Channel, or other technologies) on each of the servers.

The shared disk also has a cache on the RAID subsystem.

A cache exists in each disk drive of the array disk as well.

Fig. 4.62: Various caches

### 4.4.3 Setup example when READ (raw) is selected for the disk monitor resource

#### Example of setting up disk resources and disk monitoring

- Disk Resource
- Disk Monitor Resource (The HDDs installed in both servers are monitored in the READ (raw) mode.)
- Disk Monitor Resource (The shared disk is monitored in the READ (raw) mode.)

The following figure shows an example of two servers and a shared disk connected to them. On each internal disk of Servers 1 and 2, /dev/sda3 is specified as the disk monitor.

#### Note:

Avoid specifying any partition (e.g. one for swap) used by the OS.  
Avoid specifying any partition for possible mounting, and a whole device as well.  
Be sure to have a partition dedicated to the disk monitor resource.

On the shared disk, /dev/sdb1 is specified as the disk heartbeat, /dev/sdb2 is specified as the disk resource, and /dev/sdb3 is specified as the disk monitor.

**Note:**

Avoid specifying any partition which is already mounted or may be so in the future.  
Also avoid specifying a whole device which is already mounted or may be so in the future.  
Be sure to have a partition dedicated to the disk monitor resource.

---

Fig. 4.63: Example of configuring the disk resource and the disk monitor

#### 4.4.4 Monitor (special) tab

##### Method Server Individual Setup

Select the method used to monitor the disk device from the following:

- TUR
- TUR(generic)
- TUR(legacy)
- READ
- READ (O\_DIRECT)
- WRITE (FILE)
- READ (RAW)
- READ (VXVM)

##### Monitor Target (Within 1023 bytes) Server Individual Setup

- When the monitoring method is WRITE (FILE):  
Specify the path name of the file to be monitored. The name needs to begin with [/].  
Specify the file name with the absolute path. If you specify the file name of an existing file, it is overwritten and the data in the file is lost.
- When the monitoring method is READ (O\_DIRECT)  
Specify a path name of the device file or file to monitor. The name must begin with a forward slash (/).  
Use an absolute path of the device file name or file name.  
If a file name is specified, the file must have been created beforehand.  
Do not specify a mirror partition device (such as /dev/NMP1) as the monitor target.
- When the monitoring method is READ (RAW)  
The monitor target may be omitted. However, the monitor target raw device name must be specified. Specify this mode only when binding and monitoring the device. It is not possible to specify the device name for a partition device that has been mounted or will possibly be mounted for monitoring.  
In addition, a whole device (whole disk) of a partition device that has been mounted or will possibly be mounted cannot be specified for monitoring. Allocate a partition dedicated to monitoring. (Allocate 10 MB or more to the monitoring partition).The name must begin with a forward slash (/).

- When the monitoring method is READ (VXVM)  
The fields are dim and not selectable.
- When the monitoring method is READ  
Specify the name of the disk device or file to be used to monitor the disk device. The name must begin with a forward slash (/). If a file name is specified, the file must have been created beforehand. If a disk resource exists, the device name specified for the disk resource can be selected. If a mirror disk resource exists, the data partition device name specified for the mirror or hybrid disk resource can be selected.
- When the monitoring method is other than the above  
Specify the name of the disk device to monitor. The name must begin with a forward slash (/). If a disk resource exists, the device name specified for the disk resource can be selected. If a mirror disk resource exists, the data partition device name specified for the mirror or hybrid disk resource can be selected.

#### **Monitor Target RAW Device Name (Within 1023 bytes)** *Server Individual Setup*

This can be specified only when the monitoring method is READ (raw) or READ (VXVM).

- When the monitoring method is READ (raw)  
Enter a device name for raw accessing. A raw device that is already registered in the Disk I/F list under the server properties cannot be registered. Select READ (VXVM) as the monitoring method when monitoring a VxVM volume raw device.
- When the monitoring method is READ (VXVM)  
Specify a VxVM volume raw device name. The READ (VXVM) monitoring method can be used only when the file system of the volume raw device is vxfs. The name must begin with a forward slash (/).
  - To create an association with a disk resource, specify the dependent disk resource for **Target Resource** in "*Monitor (common) tab*" Specify that monitoring start after the specified disk resource is activated.

#### **I/O Size (1 to 99999999)** *Server Individual Setup*

Specify the size of I/O for reading or reading/writing when READ or WRITE (FILE) is selected as a monitoring method.

- When READ (RAW) , READ(O\_DIRECT) or READ (VXVM) is specified, the **I/O size** text box is dim. A single sector is read from the target device.
- If TUR, TUR (generic), or TUR (legacy) is specified, this setting is ignored.

#### **Action When Diskfull is Detected** *Server Individual Setup*

Select the action when diskfull (state in which the disk being monitored has no free space) is detected.

- Recover  
The disk monitor resource recognizes an error upon the detection of disk full.
- Do not recover  
The disk monitor resource recognizes a caution upon the detection of disk full.

---

**Note:** If READ, READ (RAW), READ (VXVM), READ (O\_DIRECT), TUR, TUR (generic), or TUR (legacy) is specified, the **Action when diskfull is detected** option is grayed out.

---

When a local disk is specified in **Target Device Name**, a local disk on the server can be monitored.

- Example of settings to monitor the local disk /dev/sdb by READ method, and to reboot the OS when an error is detected:

Option	Value	Remarks
Target Device Name	/dev/sdb	SCSI disk in the second machine.
Method	READ	READ method.
Recovery Target	Nothing	-
Final Action	Stop cluster service and reboot OS	Reboot the OS.

- Example of settings to monitor the local disk /dev/sdb by TUR (generic) method, and select No Operation (sending an alert to the Cluster WebUI only) as the final action when an error is detected:

Option	Value	Remarks
Target Device Name	/dev/sdb	SCSI disk in the second machine.
Method	TUR(generic)	SG_IO method
Final Action	No Operation	

## 4.5 Understanding IP monitor resources

IP monitor resource monitors IP addresses using the ping command.

### 4.5.1 Monitoring by IP monitor resources

IP monitor resource monitors specified IP addresses by using the ping command. If all IP addresses do not respond, the status is determined to be error.

To check the responses of IP addresses, packet types 0 (Echo Reply) and 8 (Echo Request) of ICMP are used.

- If you want to establish error when all of the multiple IP addresses have error, register all those IP addresses with one IP monitor resource.

The following figure shows an example of one IP monitor resource in which all IP addresses are registered. If any of the registered IP addresses are normal, IP monitor 1 considers all of them to be normal.

Fig. 4.64: One IP monitor resource where all IP addresses are registered (in normal cases)

The following figure shows an example of one IP monitor resource in which all IP addresses are registered. If all of the registered IP addresses are in error, IP monitor 1 considers so.

Fig. 4.65: One IP monitor resource where all IP addresses are registered (in error detection)

- If you want to establish error when any one of IP addresses has an error, create one IP monitor resource for each IP address.

The following figure shows an example of IP monitor resources, in each of which one IP address is registered. If there is an error of the IP address registered in any of the IP monitor resources, IP monitor 1 considers so.

Fig. 4.66: IP monitor resources, in each of which one IP address is registered (in error detection)

## 4.5.2 Monitor (special) tab

IP addresses to be monitored are listed in **IP Addresses**.

The screenshot shows a window titled "Monitor Resource Properties | ipw1" with a close button. It has four tabs: "Info", "Monitor(common)", "Monitor(special)" (which is selected), and "Recovery Action". Under the "Monitor(special)" tab, there is a section labeled "Common" with sub-labels "server1" and "server2". Below this are three buttons: "Edit", "Add", and "Remove". Further down is a section titled "IP Address List" with a sub-label "IP Address". A table below this contains one entry: "192.168.0.1". At the bottom right are three buttons: "OK", "Cancel", and "Apply".

### Add

Click **Add** to add an IP address to be monitored. A dialog box where an IP address can be entered is displayed.

The screenshot shows a dialog box titled "IP Address Settings". It contains a label "IP Address\*" followed by a text input field. At the bottom right are two buttons: "OK" and "Cancel".

### IP Address (Within 255 bytes) Server Individual Setup

Enter an IP address or a host name to be monitored in this field and click **OK**. The IP address or host name you enter here should be the one that exists on the public LAN. If a host name is set, the name resolution in the OS (such as adding an entry to `/etc/hosts`) should be configured.

### Remove

Click **Remove** to remove an IP address selected in **IP Addresses** from the list so that it will no longer be monitored.

### Edit

Click **Edit** to display the **IP Address Settings** dialog box. The dialog box shows the IP address selected in **IP Addresses** on the **Parameter** tab. Edit the IP address and click **OK**.

## 4.6 Understanding floating IP monitor resources

Floating IP monitor resources monitor floating IP resources.

### 4.6.1 Monitoring by floating IP monitor resources

Floating IP resources monitor floating IP resources in a server where they are activated. Floating IP monitor resources monitor whether floating IP addresses exist in the list of IP addresses. If a floating IP address does not exist in the list of IP addresses, it is determined to be an error.

Floating IP resources monitor Link Up/Down of NIC where a floating IP address is active. If NIC link down is detected, it is considered as an error. In some NIC boards and drivers, the required ioctl() may not be supported. In such a case, monitoring cannot be performed.

You can check the availability of the NIC Link Up/Down monitor by using the [ethtool] command provided by the distributor. For the check method using the [ethtool] command, see "[Note on NIC Link Up/Down monitor resources](#)" in "[Understanding NIC Link Up/Down monitor resources](#)" of this guide.

### 4.6.2 Note on floating IP monitor resources

- This monitor resource is automatically registered when a floating IP resource is added. A floating IP monitor resource corresponding to a floating IP resource is automatically registered.

Floating IP monitor resources are initially defaulted, so configure appropriate resource settings as needed.

### 4.6.3 Monitor (special) tab

Monitor Resource Properties | fipw1

Info Monitor(common) **Monitor(special)** Recovery Action

Common server1 server2

Monitor NIC Link Up/Down ☐

OK Cancel Apply

#### Monitor NIC Link Up/Down

Specify whether to monitor NIC Link Up/Down. If you have enabled, you can monitor the NIC Link Up/Down for the NIC that granted the floating IP. For this reason, a new set of NIC Link Up/Down monitor resource for the NIC that granted the floating IP is not required.

## 4.7 Understanding NIC Link Up/Down monitor resources

### 4.7.1 System requirements for NIC Link Up/Down monitor resource

#### Network interfaces supporting NIC Link Up/Down monitor resource

NIC Link Up/Down monitor resource has been tested to work in the following network interfaces.

Ethernet Controller(Chip)	Bus	Driver version
Intel 82557/8/9	PCI	3.5.10-k2-NAPI
Intel 82546EB	PCI	7.2.9
Intel 82546GB	PCI	7.3.20-k2-NAPI 7.2.9
Intel 82573L	PCI	7.3.20-k2-NAPI
Intel 80003ES2LAN	PCI	7.3.20-k2-NAPI
Broadcom BCM5721	PCI	7.3.20-k2-NAPI

### 4.7.2 Note on NIC Link Up/Down monitor resources

Some NIC boards and drivers do not support required `ioctl()`.

Use the `ethtool` command distributors provide to check whether or not NIC Link Up/Down monitor resource runs. .

```
ethtool eth0
Settings for eth0:
    Supported ports: [ TP ]
    Supported link modes:   10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Supports auto-negotiation: Yes
    Advertised link modes:  10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Advertised auto-negotiation: Yes
    Speed: 1000Mb/s
    Duplex: Full
    Port: Twisted Pair
    PHYAD: 0
    Transceiver: internal
    Auto-negotiation: on
    Supports Wake-on: umbg
    Wake-on: g
    Current message level: 0x00000007 (7)
    Link detected: yes
```

- When the LAN cable link status ("Link detected: yes") is not displayed in the result of the `ethtool` command:
  - It is highly likely that NIC Link Up/Down monitor resource of EXPRESSCLUSTER is unable to operate. Use the IP monitor resource instead.
- When LAN cable link status ("Link detected: yes") is displayed in the result of the `ethtool` command:

- In most cases NIC Link Up/Down monitor resource of EXPRESSCLUSTER can operate, but sometimes it may not operate.
- Particularly in the following hardware, NIC Link Up/Down monitor resource of EXPRESSCLUSTER may not operate. Use IP monitor resource instead.

\* When hardware is installed between the actual LAN connector and NIC chip such as a blade server

When you check if NIC Link Up/Down monitor resource can be used with the use of EXPRESSCLUSTER on a machine for a production environment, follow the steps below.

1. Register NIC Link Up/Down monitor resource with the configuration data.  
Select **No Operation** for the configuration of recovery operation of NIC Link Up/Down monitor resource upon failure detection.
2. Start the cluster.
3. Check the status of NIC Link Up/Down monitor resource.  
If the status of NIC Link Up/Down monitor resource is abnormal while LAN cable link status is normal, NIC Link Up/Down monitor resource cannot be used.
4. If NIC Link Up/Down monitor resource status becomes abnormal when LAN cable link status is made abnormal status (link down status), (NIC Link Up/Down monitor resource can be used).  
If the status remains to be normal, NIC Link Up/Down monitor resource cannot be used.

### 4.7.3 Configuration and range of NIC Link Up/Down monitoring

An error in NIC Link Up/Down monitoring can be caused by more than one factor. In an attempt to connect a server to a network device via a LAN cable, the cable may not be connected at the side of the server or of the network device; the network device may be disconnected from the power source.

Fig. 4.67: NIC Link Up/Down monitoring and its error causes

- The `ioctl()` to the NIC driver is used to find how the server is linked to the network. (For the IP monitoring, the status is judged by the ping response from the specified IP address.)
- You can monitor an NIC dedicated to interconnect (mirror connect). If you do this in the environment where two nodes are directly connected with a LAN cable and one server fails, the other server is considered to be failing. This is because no link is established. The recovery action to be taken at detection of error should be configured with the appropriate value. For example, if **Stop cluster daemon and reboot OS** is selected, other servers will continue to restart the OS endlessly.

If the network is has a bonding status, it is possible to monitor the master interface (bond0...) as well as the slave interface (eth0, eth1...) in the lower level, while applying the bonding availability. It is recommended to use the settings below.

- Slave Interface Recovery action when an error is detected: Set no action

- When only one of the network cables (eth0) fails, EXPRESSCLUSTER issues an alert, while no recovery action takes place. The network recovery is performed by bonding.
- Master Interface
  - Recovery action when an error is detected: Set actions such as failover and shutdown. When all slave interfaces fail (and the master interface is down), the EXPRESSCLUSTER performs the recovery action.

The following figure shows a case of slave interfaces (eth0 and eth1) in a bonding status and the master interface (bond0).

When an error occurs in eth0, the bonding driver performs degeneration or switching.

Fig. 4.68: Example of using network bonding

#### 4.7.4 Monitor (special) tab

NIC Link Up/Down monitor resource obtains the information on how the specified NIC is linked monitors the linkage is up or down.

Monitor Resource Properties | miiw1

Info Monitor(common) Monitor(special) Recovery Action

Common server1 server2

Monitor Target\* eth0

OK Cancel Apply

**Monitor Target** (Within 15 bytes) Server Individual Setup

Enter the name of the NIC interface you want to monitor. You can monitor Bond devices (e.g. bond.600) and team devices (e.g. team0). You can also monitor VLAN and tagVLAN (setting example: eth0.8).

## 4.8 Understanding mirror disk connect monitor resources

### 4.8.1 Note on mirror disk connect monitor resources

- A mirror disk connect monitor resource monitors a network for mirroring. If communication of mirror data using the specified mirror disk connect fails, it is recognized as an error. This resource is automatically registered when the mirror disk resource is added.
- When more than one mirror disk resource is added, the same number of mirror disk connect monitor resources as the one of mirror resources is automatically registered.

### 4.8.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | mdnw1" with a close button "mdnw X". Inside the window, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Below the tabs, there is a label "Mirror Disk Resource" followed by a text input field containing "md1" and a "Browse" button. At the bottom right of the window, there are three buttons: "OK", "Cancel", and "Apply".

#### Mirror Disk Resource

The mirror disk resource to be monitored is displayed.

## 4.9 Understanding mirror disk monitor resources

Mirror disk monitor resources monitor the state of date of mirror disk and the soundness of mirror driver.

### 4.9.1 Note on mirror disk monitor resources

This resource is automatically registered when a mirror disk resource is added. A mirror disk monitor resource corresponding to a mirror disk resource is automatically registered.

### 4.9.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | mdw1" with a close button "mdw X". Inside the window, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Below the tabs, there is a label "Mirror Disk Resource" followed by a text input field containing "md1" and a "Browse" button. At the bottom right of the window, there are three buttons: "OK", "Cancel", and "Apply".

#### Mirror Disk Resource

The mirror disk resource to be monitored is displayed.

## 4.10 Understanding hybrid disk connect monitor resources

### 4.10.1 Note on hybrid disk connect monitor resources

- A mirror disk connect monitor resource monitors a network for mirroring. If communication of mirror data using the specified mirror disk connect fails, it is recognized as an error. This resource is automatically registered when the hybrid disk resource is added.
- When more than one hybrid disk resource is added, hybrid disk connect monitor resources as many as the number of the hybrid disk resources are automatically registered.

### 4.10.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | hdnw1" with a close button "hdnw X". Inside the window, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Below the tabs, there is a label "Hybrid Disk Resource" followed by a text input field containing "hd1" and a "Browse" button. At the bottom right of the window, there are three buttons: "OK", "Cancel", and "Apply".

#### Hybrid Disk Resource

The hybrid disk resource to be monitored is displayed.

## 4.11 Understanding hybrid disk monitor resources

Hybrid disk monitor resources monitor the status of the data in the hybrid disk and the health of the mirror driver.

### 4.11.1 Note on hybrid disk monitor resources

This resource is automatically registered when a hybrid disk resource is added. Hybrid disk monitor resources corresponding to hybrid disk resources are automatically registered.

### 4.11.2 Monitor (special) tab

#### Hybrid Disk Resource

The hybrid disk resource for monitoring is displayed.

## 4.12 Understanding PID monitor resources

### 4.12.1 Note on PID monitor resources

PID monitor resource monitors a successfully activated EXEC resource. The EXEC resource can be monitored if its settings for activation are configured to **Asynchronous**.

### 4.12.2 Setting PID monitor resources

PIC monitor resource monitors a successfully activated EXEC resource. By monitoring the presence of process ID, an error is established when the process ID disappears.

The exec resource to be monitored is set according to the steps described in "Target Resource" of "*Monitor (common) tab*". The exec resource can be monitored if its settings for activation are configured to **Asynchronous**. You cannot detect stalled status of the process.

---

**Note:** To monitor stalls such as data base, samba, apache, and sendmail, purchase optional EXPRESSCLUSTER product.

---

## 4.13 Understanding User mode monitor resources

### 4.13.1 Drivers that User mode monitor resources depend

#### Monitor by: **softdog**

softdog

- If softdog is selected as a monitoring method, the softdog driver is required.
- Use a loadable module configuration. User-mode monitor resources do not work on the static driver.
- If the softdog driver is not available, monitoring cannot be started.

#### Monitor by: **keepalive**

clpka

clpkhb

- If keepalive is selected as a monitoring method, the clpkhb driver and the clpka driver of the EXPRESSCLUSTER are required.
- When keepalive is set to the monitoring method, it is recommended to set the kernel mode LAN heartbeat. To use the kernel mode LAN heartbeat, the clpkhb driver is required.
- The clpka driver and the clpkhb driver are provided by EXPRESSCLUSTER. For information on support, refer to "Supported distributions and kernel versions" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".
- You cannot start monitoring if the clpkhb driver and the clpka driver cannot be used.

#### Monitor by: **ipmi, ipmi (High-End Server Option)**

ipmi

- If ipmi or ipmi (High-End Server Option) is used as a monitoring method, this driver is required.
- If the ipmi driver is not loaded, monitoring cannot be started.

### 4.13.2 How monitor User mode monitor resources perform monitoring

You can select how a user-mode monitor resource monitors its target from the following:

#### Monitor by: **softdog**

If softdog is selected as a monitoring method, the softdog driver of the OS is used.

#### Monitor by: **keepalive**

If keepalive is selected as a monitoring method, the clpkhb and the clpka drivers are used.

---

**Note:** Always check the distributions and the kernel versions on which the clpkhb driver and the clpka driver can be operated with "Supported distributions and kernel versions" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide". Check them when applying a security patch released by a distributor to the operating cluster (when the kernel version changes).

---

#### Monitor by: **ipmi, ipmi (High-End Server Option)**

If ipmi or ipmi (High-End Server Option) is selected as a monitoring method, the ipmi driver is used.

#### Monitor by: **none**

"none" is a monitoring method is used for evaluation. This only executes operations of the advanced settings of the user-mode monitor resource. Do not use this in a production environment.

### 4.13.3 Advanced settings of User mode monitor resource

Opening/closing of a dummy file, writing to a dummy file and creating a dummy thread are the configurations that allow advance user-mode monitor resource. If any of these configurations fail, the timer will not be updated. If a configuration continues to fail for the period of time set for the timeout or heartbeat timeout, the OS is reset.

#### Opening/closing a dummy file

A dummy file is created, opened, closed and then deleted at every monitoring interval repeatedly.

- When this advanced function is set and there is no free disk space, opening the dummy file fails and the OS is reset.

#### Writing to a dummy file

A specified size of data is written into a dummy file at every monitoring interval.

- This advanced function is not available unless opening/closing a dummy file is set.

#### Creating a dummy thread

A dummy thread is created at every monitoring interval.

### 4.13.4 User mode monitor resource logic

The following sections describe how processes and features differ by ways of monitoring. For the shutdown stall monitoring, only Step 1 in each process overview is performed.

#### Monitoring method: IPMI

- Process overview

Steps 2 to 7 of the process are repeated.

1. Set the IPMI timer
2. Open a dummy file
3. Write to the dummy file
4. Execute fdatsync for the dummy file
5. Close the dummy file
6. Create a dummy thread
7. Updated the IPMI timer

Steps 2 to 6 of the process overview are for advanced settings. To execute these steps, you need to configure the settings.

- What happens when timeout does not occur (i.e. Steps 2 to 7 are performed without any problem):  
Recovery actions such as resetting are not performed.
- What happens when timeout occurs (i.e. any of Steps 2 to 7 is stopped or delayed):  
Reset is performed by BMC (the management function of the server).
- Advantages

- This method of is less likely to be impacted by a kernel space failure, which makes chance of reset higher because BMC (the management function of the server itself) is used.
- Disadvantages
  - This method is not available on servers not supporting IPMI or on which OpenIPMI does not run. This is because this monitoring method is hardware dependent.
  - This method is not available on a server where NEC ESMPRO Agent is used.
  - This method may not be able to coexist with software programs for server monitoring that are supplied by server vendors.

#### **Monitoring method: softdog**

- Process overview

Steps 2 to 7 of the process are repeated.

1. Set softdog
2. Open a dummy file
3. Write to the dummy file
4. Execute fdatasync for the dummy file
5. Close the dummy file
6. Create a dummy thread
7. Update the softdog timer

Steps 2 to 6 of the process overview are for advanced settings. To execute these steps, you need to configure the settings.

- What happens when timeout does not occur (i.e. Steps 2 to 7 are performed without any problem):  
Recovery actions such as reset are not performed.
- What happens when timeout occurs (i.e. any of Steps 2 to 7 is stopped or delayed):  
Reset is performed by softdog.
- Advantages
  - Since this method is not dependent on hardware, you can use it as long as there is a softdog kernel module.  
(In some distributions, softdog is not provided by default. Check that you have softdog before configuring the settings.)
- Disadvantages
  - Because softdog is dependent on the timer logic of the kernel space, reset may not be performed if an error occurs in the kernel space.

#### **Monitoring method: keepalive**

- Process overview

Steps 2 to 7 are repeated.

1. Set the keepalive timer
2. Open a dummy file
3. Execute write to the dummy file
4. Execute fdatasync to the dummy file

5. Close the dummy file
6. Create a dummy thread
7. Update the keepalive timer

Steps 2 to 6 of the process overview are for advanced settings. To execute these steps, you need to configure the settings

- When a timeout does not occur (i.e. Steps 2 to 7 are performed without any problem): Recovery actions such as reset are not performed.
- When a timeout occurs (i.e. any of Steps 2 to 7 is stopped or delayed):
  - Reset of the local server is announced to other servers through clpkhb.ko.
  - Reset or panic is performed by clpka.ko according to the action setting.
- Advantage
  - Logs are recorded on other servers by announcement of the reset of the local server through execution of clpkhb.
- Disadvantages
  - Distributions, architectures, kernel versions which can be operated (which provide drivers) are limited.
  - Because clpka is dependent on the timer logic of the kernel space, reset may not be performed if an error occurs in the kernel space.

**Monitoring method: ipmi (High-End Server Option)**

- It can't be used.

### 4.13.5 Checking availability of IPMI

You can quickly check if OpenIPMI runs on the server by following the steps below:

1. Install the rpm package of OpenIPMI.
2. Run `/usr/bin/ipmitool`.
3. Check the result of the execution.

**When you see the following (the result of `/usr/bin/ipmitool bmc watchdog get`):**

(This is an example. Different values may be shown depending on your hardware devices.)

```
Watchdog Timer Use: BIOS FRB2 (0x01)
Watchdog Timer Is: Stopped
Watchdog Timer Actions: No action (0x00)
Pre-timeout interval: 0 seconds
Timer Expiration Flags: 0x00
Initial Countdown: 0 sec
Present Countdown: 0 sec
```

You can use OpenIPMI. ipmi can be chosen as a monitoring method.

### 4.13.6 User mode monitor resources

#### All monitoring methods:

- When a cluster is added by the Cluster WebUI, a user-mode monitor resource of softdog is automatically created.
- A user-mode monitor resource with different monitoring method can be added. A user-mode monitor resource of softdog that was automatically created can be deleted when a cluster is added.
- When the activation of a user-mode monitor resource fails due to a reason such as the softdog driver of OS or the clpkhb/clpka driver of EXPRESSCLUSTER does not exist, or the rpm for OpenIPMI is not installed, "Monitor userw failed." will be displayed on the Alert logs in the Cluster WebUI,. In the tree view of the Cluster WebUI, as the response to the clpstat command, Normal will be displayed as the resource status, and Offline will be displayed as the status of each server.

#### Monitoring by IPMI:

- For notes on ipmi, see "*IPMI command*" in "*Monitor resource*" in "*4. Monitor resource details*" in this guide.

---

#### Note:

If you are using a software program for server monitoring provided by a server vendor such as NEC ESMPRO Agent, do not choose IPMI as a monitoring method.

Because these software programs for server monitoring and OpenIPMI both use BMC (Baseboard Management Controller) on the server, a conflict occurs, preventing successful monitoring.

---

#### Monitoring by ipmi (High-End Server Option)

- It can't be used.

#### Monitoring by keepalive

- Notification to other servers are performed only when a kernel mode LAN heartbeat resource is set. In this case, the following log is displayed on the syslog.

```
kernel: clpka: <server priority: %d> <reason: %s> <process name: %s>system reboot.
```

### 4.13.7 Monitor (special) tab

User-mode monitor resource considers stalling in user space as an error.

This resource is automatically registered when a cluster is added. The user-mode monitor resource of softdog is automatically registered. The monitoring method is softdog.

Monitor Resource Properties | userw1

Info Monitor(common) **Monitor(special)** Recovery Action

Use heartbeat interval and timeout ☒

Method\* keepalive

Operation at Timeout Detection\* RESET

Extended Monitor Settings

Open/Close Temporary File ☐

Write ☐

Size 10000 byte

Create Temporary Thread ☐

OK Cancel Apply

#### Use heartbeat interval and timeout

Select this check box if you use heartbeat's interval and timeout for monitor's interval and timeout.

- When the check box is selected:  
Heartbeat interval and timeout are used.
- When the check box is not selected:  
Heartbeat is not used. Interval and timeout specified on the **Monitor** tab are used.  
You need to set a larger value for timeout than interval.  
When ipmi is specified to **Method**, you need to specify 255 or less for timeout.

#### Method

Choose how you want to monitor the user-mode monitor resource from the following.

You can not select a method which has already been used for other user-mode monitor resource.

- softdog:  
Uses softdog driver
- ipmi:  
Uses OpenIPMI
- ipmi(High-End Server Option):  
It can't be used.
- keepalive:  
Uses clpkhb driver and clpka driver.
- No Operation:

Uses nothing.

### **Operation at Timeout Detection**

Select the final action. This can be set only when the monitoring method is keepalive.

- **RESET:**  
Resets the server.
- **PANIC:**  
Performs a panic of the server.
- **IOFENCING:**  
It can't be used.

### **Open/Close Temporary File**

Select this check box if you want to open/close a dummy file at every interval when you execute monitoring.

- When the check box is selected:  
A dummy file will be opened/closed.
- When the check box is not selected:  
A dummy file will not be opened/closed.

### **Write**

Select this check box if you have chosen to open/close a dummy file and want to write in dummy data.

- When the check box is selected:  
Dummy data is written into a dummy file.
- When the check box is not selected:  
Dummy data is not written into a dummy file.

### **Size (1 to 9999999)**

If you have chosen to write dummy data into a dummy file, specify the size to write in.

### **Create Temporary Thread**

Select this check box if you want to create a dummy thread when monitoring is performed.

- When the check box is selected:  
Temporary thread will be created.
- When the check box is not selected:  
Temporary thread will not be created.

## 4.14 Understanding multi target monitor resources

The multi target monitor resource monitors more than one monitor resources.

### 4.14.1 Notes on multi target monitor resources

- The multi target monitor resources regard the offline status of registered monitor resources as being an error. For this reason, for a monitor resource that performs monitoring when the target is active is registered, the multi target monitor resource might detect an error even when an error is not detected by the monitor resource. Do not, therefore, register monitor resources that perform monitoring when the target is active.

### 4.14.2 Multi target monitor resource status

The status of the multi target monitor resource is determined by the status of registered monitor resources.

The table below describes status of multi target monitor resource when the multi target monitor resource is configured as follows:

The number of registered monitor resources 2

Error Threshold 2

Warning Threshold 1

Multi target monitor resource status		Monitor resource1 status		
		Normal	Error	Offline
Monitor resource2 status	Normal	normal	caution	caution
	Error	caution	error	error
	Offline	caution	error	normal

- Multi target monitor resource monitors status of registered monitor resources.  
If the number of the monitor resources with the error status exceeds the error threshold, the status of the multi target monitor resource becomes error.  
If the number of the monitor resources with the caution status exceeds the caution threshold, the status of the multi target resource becomes caution.  
If all registered monitor resources are in the status of stopped (offline), the status of multi target monitor resource becomes normal. Unless all the registered monitor resources are stopped (offline), the multi target monitor resource recognizes the stopped (offline) status of a monitor resource as error.
- If the status of a registered monitor resource becomes error, actions for the error of the monitoring resource are not executed.  
Actions for error of the multi target monitor resource are executed only when the status of the multi target monitor resource becomes error.

#### 4.14.3 Example of the multi target monitor resource configuration

- An example of disk path duplication driver usage

The status should be indicating an error only when disk devices (for example, /dev/sdb and /dev/sdc) fail at the same time.

The following figure shows a path-duplicating configuration with two HBAs and a disk path duplication driver. When an error occurs in one of the HBAs, the disk path duplication driver performs path degeneration or switching.

Fig. 4.69: Example of using a disk path duplication driver

- Monitor resources to be registered with the multi target monitor resources (mtw1):
  - \* diskw1
  - \* diskw2
- Error Threshold and Warning Threshold of multi target monitor resource (mtw1)
  - \* Error Threshold 2
  - \* Warning Threshold 0
- Detailed settings of the monitor resource to be registered with the multi target monitor resource (mtw1)
  - \* Disk monitor resource (diskw1)
    - Target Device Name: /dev/sdb
    - Reactivation Threshold: 0
    - Failover Threshold: 0
    - Final Action: No Operation
  - \* Disk monitor resource (diskw2)
    - Target Device Name: /dev/sdc

Reactivation Threshold: 0  
Failover Threshold: 0  
Final Action: No Operation

- With the settings above, even if either of diskw1 and diskw2, which are registered as monitor resources of the multi target monitor resource detects an error, no actions for the monitor resource having the error are taken.
- Actions for an error set to the multi target monitor resource are executed when the status of both diskw1 and diskw2 become error, or when the status of two monitor resources become error and offline.

#### 4.14.4 Monitor (special) tab

Monitor resources are grouped and the status of the group is monitored. You can register up to 64 monitor resources in the **Monitor Resources**.

When the only one monitor resource set in the **Monitor Resources** is deleted, the multi target monitor resource is deleted automatically.

Monitor Resource Properties | mtw1 mtw X

##### Add

Click **Add** to add a selected monitor resource to **Monitor Resources**.

##### Remove

Click **Remove** to delete a selected monitor resource from **Monitor Resources**.

##### Tuning

Open **Multi Target Monitor Resource Tuning Properties** dialog box. Configure detailed settings for the multi target monitor resource.

#### MultiTarget Monitor Resource Tuning Properties

##### Parameter tab

Display the details of setting the parameter

**MultiTarget Monitor Resource Tuning Properties**

Parameter

**Failure Threshold**  
☒ Same as Number of Members  
☐ Specify Number 64

**Warning Threshold**  
☐ Specify Number

Initialize

OK Cancel Apply

### Error Threshold

Select the condition for multi target monitor resources to be determined as an error.

- Same as Number of Members

The status of multi target monitor resources becomes "Error" when all monitor resources specified to be under the multi target monitor resource are failed, or when "Error" and "Offline" co-exist.

The status of multi target monitor resources becomes "Normal" when the status of all monitor resources specified to be under the multi target monitor resource are "Offline."

- Specify Number

The status of multi target monitor resources becomes "Error" when the number of monitor resources specified in **Error Threshold** becomes "Error" or "Offline."

When the status of some monitor resources among those specified to be under the multi target monitor resource, specify how many monitor resources need to be "Error" or "Offline" to determine that the status of multi target monitor resource is "Error."

### Warning Threshold

- When the check box is selected:

When the status of some monitor resources among those specified to be under the multi target monitor resource, specify how many monitor resources need to be "Error" or "Offline" to determine that the status of multi target monitor resource is "Caution."

- When the check box is not selected:

Multi target monitor resources do not display an alert.

### Initialize

Clicking **Initialize** resets all items to their default values.

## 4.15 Understanding virtual IP monitor resources

### 4.15.1 Note on virtual IP monitor resources

Detailed settings are not required for virtual IP monitor resources.

Use the resources when using virtual IP resources of EXPRESSCLUSTER.

- Virtual IP monitor resource is created automatically when the virtual IP resource is created. One virtual IP monitor resource is created per virtual IP resource automatically.
- Virtual IP monitor resource cannot be deleted. It is deleted automatically at deletion of a virtual IP resource.
- Do not change the recovery target.
- Monitoring cannot be suspended or resumed by the clpmonctrl command or the Cluster WebUI.
- Virtual IP monitor resource regularly sends RIP packets to control a path of the virtual IP resource. If the target virtual IP resource is active while the cluster is suspended, the virtual IP monitor resource continues operating.
- The setting of Monitor(common) tab-Retry Count is invalid. When you'd like to delay error detection, please change the setting of Monitor(common) tab-Timeout.

### 4.15.2 Setting virtual IP monitor resources

Virtual IP monitor resource sends packets for dynamic routing of the routing table the virtual IP resource requires. The status of IP addresses activated by the virtual IP resources is not checked. There is no detailed setting for the virtual IP monitor resource.

## 4.16 Understanding ARP monitor resources

ARP monitor resource sends ARP packets regularly to maintain and update the ARP table for active floating IP resources or virtual IP resources.

### 4.16.1 Note on ARP monitor resources

For details on the ARP broadcast packets that ARP monitor resource sends, see "*Understanding Floating IP resource*" of "3. *Group resource details*" in this guide.

The status of the IP address activated by floating IP resource or virtual IP resource is not checked.

Only floating IP resource or virtual IP resource can be selected as a target monitoring resource of ARP monitor resource. On the ARP monitor resource setting, make sure to select a same resource for **Target Resource** on the **Monitor(common)** tab and **Target Resource** on the **Monitor(special)** tab.

Monitoring of the ARP monitor resource cannot be suspended or resumed by the clpmonctrl command or by the Cluster WebUI.

### 4.16.2 Monitor (special) tab

The screenshot shows a dialog box titled "Monitor Resource Properties | arpw1" with a close button (X) in the top right corner. Below the title bar, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. In this tab, there is a label "Target Resource\*" followed by a text input field containing the value "fip1". To the right of the input field is a "Browse" button. At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Target Resource

Click **Browse** to display the dialog box to select a target resource. The names of groups, floating IP resources and virtual IP resources registered to a LocalServer and cluster are displayed in the tree view. Select the resource you want to set as a target resource, and then click **OK**.

---

**Note:** When you change the target resource, make sure to change the one configured on the **Monitor(common)** tab.

---

## 4.17 Understanding custom monitor resources

Custom monitor resources monitor system by executing an arbitrary script.

### 4.17.1 Notes on custom resources

When the monitor type is **Asynchronous**, and the monitoring retry count is set to 1 or more, monitoring cannot be performed correctly. When you set the monitor type to **Asynchronous**, also specify 0 as the monitoring retry count.

When the Script Log Rotate function is enabled, a process is generated to mediate the log output. This intermediate process continues to work until the file descriptor is closed (i.e. until all the logs stop being output from the start and stop scripts and from a descendant process that takes over the standard output and/or the standard error output from the start and stop scripts). To exclude output from the descendant process from the log, redirect the standard output and/or the standard error output when the process is generated with the script.

### 4.17.2 Monitoring by custom monitor resources

Custom monitor resources monitor system by an arbitrary script.

When Monitor Type is **Synchronous**, custom monitor resources regularly run a script and detect errors from its error code.

When Monitor Type is **Asynchronous**, custom monitor resources run a script upon start monitoring and detect errors if the script process disappears.

### 4.17.3 Monitor (special) tab

The screenshot shows the 'Monitor Resource Properties' dialog box for a resource named 'genw1'. The 'Monitor(special)' tab is selected. The dialog has four tabs: 'Info', 'Monitor(common)', 'Monitor(special)', and 'Recovery Action'. The 'Monitor(special)' tab contains the following settings:

- File:** A text field containing 'genw.sh'. To its right are three buttons: 'Edit', 'View', and 'Replace'.
- Monitor Type:** Two radio buttons: 'Synchronous' (selected) and 'Asynchronous'.
- Wait a period of time for Application/Script monitor to start:** A text field containing '0' followed by a 'sec' unit label.
- Log Output Path:** An empty text field.
- Rotate Log:** An unchecked checkbox.
- Rotation Size:** A text field containing '1000000' followed by a 'byte' unit label.
- Normal Return Value\*:** A text field containing '0'.
- Wait for activation monitoring to stop before stopping the cluster:** An unchecked checkbox.

At the bottom right of the dialog are three buttons: 'OK', 'Cancel', and 'Apply'.

### **User Application**

Use an executable file (executable shell script file or execution file) on the server as a script. For the file name, specify an absolute path or name of the executable file of the local disk on the server.

Each executable files is not included in the cluster configuration information of the Cluster WebUI. They must be prepared on each server because they cannot be edited nor uploaded by the Cluster WebUI.

### **Script created with this product**

Use a script file which is prepared by the Cluster WebUI as a script. You can edit the script file with the Cluster WebUI if you need. The script file is included in the cluster configuration information.

### **File (Within 1023 bytes)**

Specify the script to be executed (executable shell script file or execution file) when you select User Application with its absolute path on the local disk of the server.

### **View**

Click here to display the script file when you select **Script created with this product**.

### **Edit**

Click here to edit the script file when you select **Script created with this product**. Click **Save** to apply the changes. You cannot modify the name of the script file.

### **Replace**

Click here to replace the contents of a script file with the contents of the script file which you selected in the file selection dialog box when you select **Script created with this product**. You cannot replace the script file if it is currently displayed or edited. Select a script file only. Do not select binary files (applications), and so on.

### **Monitor Type**

Select a monitor type.

- Synchronous (Default)  
Custom monitor resources regularly run a script and detect errors from its error code.
- Asynchronous  
Custom monitor resources run a script upon start monitoring and detect errors if the script process disappears.

### **Wait for the application/script monitoring to start for a certain period of time (0 to 9999)**

Specify the delay time from the start of the application/script and that of monitoring for the **Asynchronous** monitor type. This delay value must be set smaller than the timeout value specified under the **Monitor (common)** tab.

---

**Note:** The set value becomes valid next time you start the monitor.

---

Default value: 0

### **Log Output Path (Within 1023 bytes)**

Specify log output path for the script of custom monitor resource.

Pay careful attention to the free space in the file system because the log is output without any limitations when the file name is specified and the **Rotate Log** check box is unchecked.

When the **Rotate Log** check box is selected, output log files are rotated.

**Rotate Log**

Turn this off to output execution logs of scripts and executable files with no limit on the file size.

Turn it on to rotate and output the logs. In addition, note the following.

Enter the log path in 1009 bytes or less in Log Output Path. If the path exceeds 1009 bytes, the logs are not output.

The log file name must be 31 bytes or less. If the name exceeded 32 bytes, the logs are not output.

If some custom monitor resources are configured to rotate logs, and the log file names are the same but the log paths are different, the Log Rotate Size may be incorrect.

(for example, /home/foo01/log/genw.log, /home/foo02/log/genw.log)

**Rotation Size (1 to 9999999)**

Specify a file size for rotating files when the **Rotate Log** check box is selected.

The log files that are rotated and output are configured as described below.

File name	Description
Log Output Path specified_file_name	Latest log file.
Log Output Path specified_file_name.pre	Former log file that has been rotated.

**Normal Return Value (Within 1023 bytes)**

When **Asynchronous** is selected for **Monitor Type**, set the values of script error code to be determined as normal. If you want to set two or more values here, separate them by commas like 0,2,3 or connect them with a hyphen to specify the range like 0-3.

Default value: 0

**Wait for activation monitoring to stop before stopping the cluster**

The cluster stop waits until the custom monitor resource is stopped. This is effective only when the monitoring timing is set to **Active**.

## 4.18 Understanding volume manager monitor resources

Volume manager monitor resources are used to monitor logical disks managed by the volume manager.

### 4.18.1 Notes on volume manager monitor resources

When the volume manager is VxVM, volmgrw uses the daemon monitoring method. Therefore, registering multiple items in a single cluster is meaningless.

When specifying VxVM as the volume manager, do not specify the recovery target.

Volume manager monitor resources are automatically registered when a volume manager resource is added. Volume manager monitor resources are automatically registered to the volume manager resource.

Volume manager monitor resources are configured with their default settings; change the settings as needed.

Registering the volmgr resource does not automatically register the volmgrw monitor. The volmgrw monitor must be registered manually.

When monitoring the LVM by using the volume manager monitor resource in an environment of Red Hat Enterprise Linux 7 or later, the LVM metadata daemon must be disabled.

### 4.18.2 Monitoring by volume manager monitor resources

The monitoring method used by volume manager monitor resources depends on the type of volume manager that manages the target logical disks.

The following volume managers are supported:

- lvm (LVM volume group)
- vxvm (VxVM daemon)
- zfspool (ZFS storage pool)

### 4.18.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | volmgrw1" with a close button "volmgrw X". Inside, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is selected. It contains two fields: "Volume Manager\*" with a dropdown menu showing "lvm", and "Target Name\*" with a text box containing "vg1". At the bottom right are three buttons: "OK", "Cancel", and "Apply".

#### Volume Manager

Specify the type of volume manager that manages the monitor target logical disks. The following volume managers are supported:

- lvm (LVM volume group)

- vxvm (VxVM daemon)
- zfspool (ZFS storage pool)

**Target Name**(within 1023 bytes)

Specify the name of the monitor target in the <VG name> format (only the target name is used).

When the volume manager is lvm, it's possible to control multiple volumes together.

More than one volume is delimited with an one-byte space.

When the volume manager is vxvm, this setting need not be entered.

## 4.19 Understanding message receive monitor resources

Message receive monitor resources are passive monitors. They do not perform monitoring by themselves.

When an error message issued using the `clprexec` command is received from outside of EXPRESSCLUSTER, the message receive monitor resources change their status and perform recovery from the error.

### 4.19.1 Monitoring by message receive monitor resources

- When an error message is received from an outside source, the resource recovers the message receive monitor resource whose Category and Keyword have been reported. (The Keyword can be omitted.)  
If there are multiple message receive monitor resources whose monitor types and monitor targets have been reported, each monitor resource is recovered.
- Message receive monitors can receive error messages issued by the `clprexec` command, local server BMC, and expanded device drivers within the server management infrastructure.
- Error messages from local server BMC are available only in Express5800/A1080a or Express5800/A1040a series linkage. For details, see "Express5800/A1080a or Express5800/A1040a series linkage with message receive monitor resources" in "Express5800/A1080a or Express5800/A1040a series linkage" in "Linkage with specific hardware" in the "Hardware Feature Guide".
- For details on the monitoring method that uses linkage with server management infrastructure, see "Linkage with Server Management Infrastructure" in the "Hardware Feature Guide".

The following figure shows an example of a configuration with a message receive monitor resource. Receiving an error message issued by the `clprexec` command, the message receive monitor resource of Server 2 changes its own status and starts a recovery from the detected error.

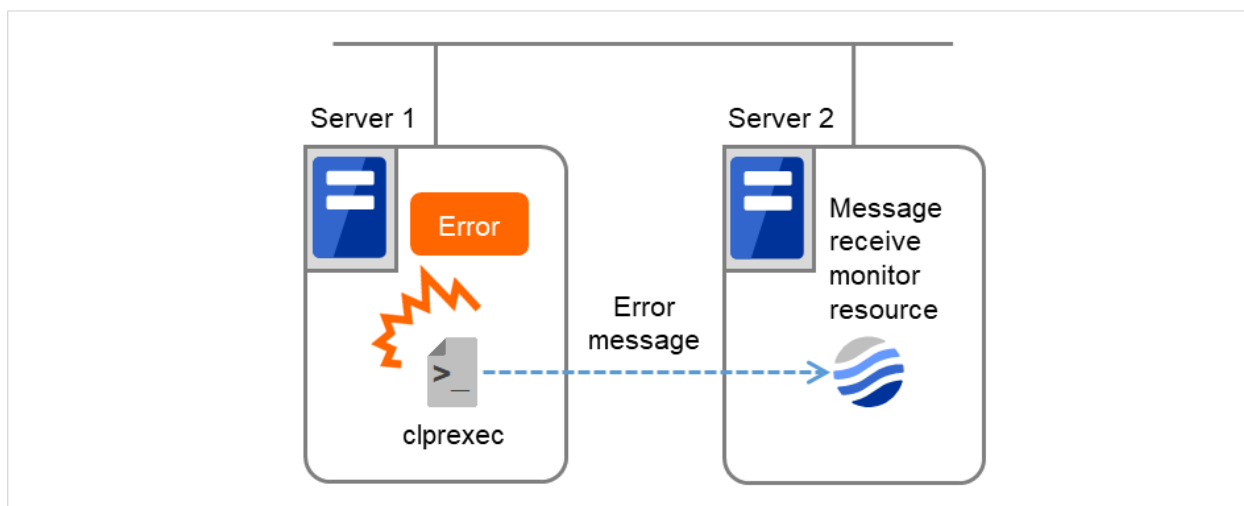

Fig. 4.70: Configuration with a message receive monitor resource

### 4.19.2 Failover to outside the server group

- Upon the reception of notification of the occurrence of an error, failover from the active server group to another server group is allowed.
- The following server group and other settings must be specified.
  - Group resource for recovery
    - \* [Use Server Group Settings] is selected
  - Message receive monitor
    - \* [Execute failover to the recovery target] is specified for the recovery target
    - \* [Execute Failover outside the Server Group] is selected
- Upon the execution of server group failover to outside the server group, the dynamic failover settings and inter-server group failover settings are disabled. The server fails over to the server having the highest priority in a server group other than that to which it belongs.

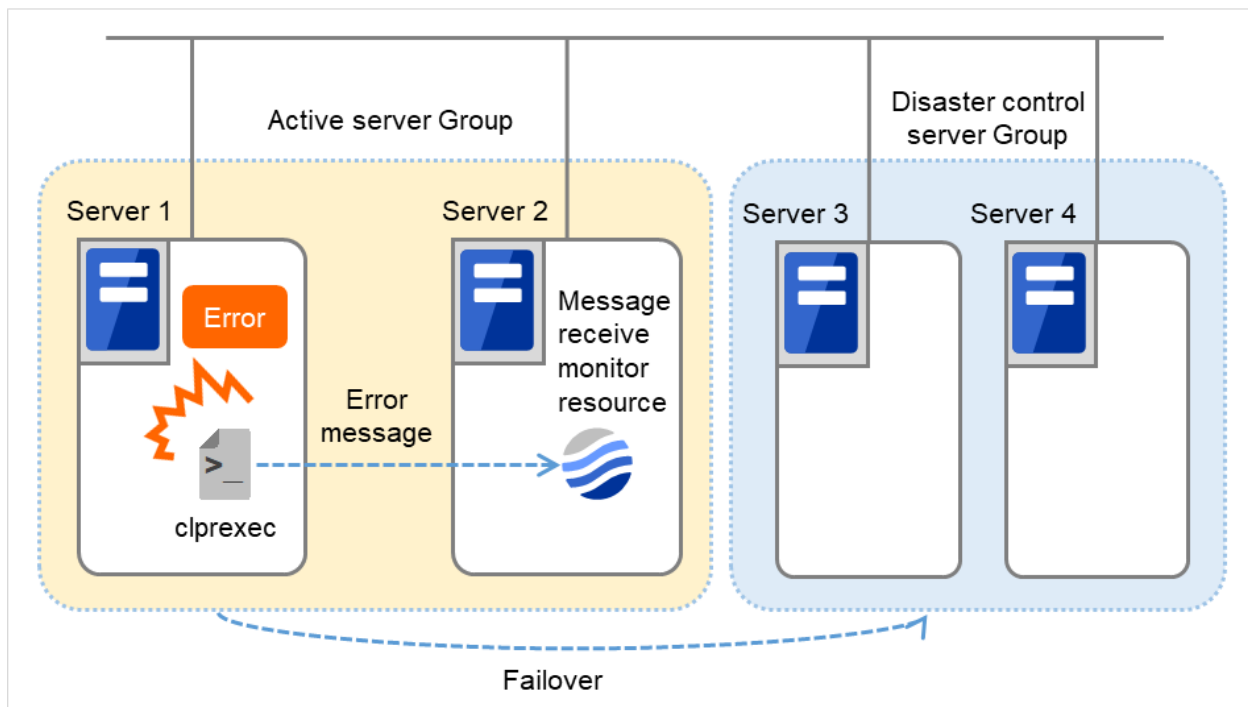

Fig. 4.71: Configuration with a message receive monitor resource (in failing over to another server group)

### 4.19.3 Notes on message receive monitor resources

Notes on message receive monitor resources

- If a message receive monitor resource is paused when an error message is received from outside, error correction is not performed.
- If an error message is received from outside, the status of the message receive monitor resource becomes "error". The error status of the message receive monitor resource is not automatically restored to "normal". To restore the status to normal, use the `clprexec` command. For details about this command, see ["Requesting"](#)

*processing to cluster servers (clprexec command)" in "8. EXPRESSCLUSTER command reference" in this guide.*

- If an error message is received when the message receive monitor resource is already in the error status due to a previous error message, recovery from the error is not performed.

When the recovery action is **Executing failover to outside the Server Group**, and if **Execute Failover to outside the Server Group** is selected, the server always fails over to a server in a server group other than the active server group. If, however, the above-mentioned settings are configured but the server group is not configured, the failover destination is determined according to the ordinary failover policy.

- To receive an I/O Fencing completion notification from the BMC, the management LAN port of the BMC must be capable of communicating with the NIC of the OS. Specify a port number by connecting the SNMP Trap-receiving IP addresses of all servers with ; (semicolon). The port number can be omitted (defaults to 162). If it is necessary to set a port number, it must be entered at the end of the IP address, after : (colon).

Example: 192.168.0.1;192.168.0.2;192.168.0.3:162

Notes on using the Express5800/A1080a or Express5800/A1040a series linkage function

- To enable the reception of error messages from BMC, the hardware and firmware on the server must be configured accordingly. The IPMI service must also be activated. For details on supported hardware, see "Servers supporting Express5800/A1080a or Express5800/A1040a series -related functions" in the "Getting Started Guide".
- To enable the reception of error messages from BMC, communication from the BMC network interface to the OS network interface must be secured.
- To enable the reception of error messages from BMC, specify the IP address for SNMP trap reception and the port number for the server by using server-specific settings. The port number can be omitted (defaults to 162). Configure the same port number for all message receive monitor resources on the server if explicitly specified.

Notes on using linkage with server management infrastructure

- If the Enterprise Linux with Dependable Support server management infrastructure is linked, the settings for and operation of the message receive monitor resources will differ. If linking with the server management infrastructure, see "Linkage with Server Management Infrastructure" in the "Hardware Feature Guide".

#### 4.19.4 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | mrw1" with a close button (X) in the top right corner. Below the title bar are four tabs: "Info", "Monitor(common)", "Monitor(special)" (which is selected), and "Recovery Action". Under the "Monitor(special)" tab, there are three sections. The first section, "Common", has sub-tabs for "server1" and "server2". The "Category\*" dropdown menu is set to "NIC". Below it is an empty "Keyword" text box. The second section, "High-End Server Option", contains two checkboxes: "Set monitor status to Stall because of BMC detected predict failure" and "Set monitor status to Stall because of BMC detected performance down", both of which are currently unchecked. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

For **Category** and **Keyword**, specify a keyword passed using the -k parameter of the clprexec command. The keyword can be omitted.

**Category** (within 32 bytes)

Specify a monitor type. To monitor error messages from BMC (SNMP Trap), specify BMCNOTICE.

You can select the default character string from the list box or specify any character string.

**Keyword** (within 1023 bytes)

Specify a keyword passed using the -k parameter of the clprexec command. When BMCNOTICE is specified for the category, specify the IP address for SNMP trap reception and the port number for each server by using server-specific settings. The port number can be omitted (defaults to 162). Configure the same port number for all the message receive monitor resources for each server if explicitly specified. The specification format is as described below:

`<IP_address>[:<port_number>]`

**Set monitor status to Stall because of BMC detected predict failure**

This cannot be used.

**Set monitor status to Stall because of BMC detected performance down**

This cannot be used.

## 4.19.5 Recovery Action tab

Specify the recovery target and the action upon detecting an error. For message receive monitor resources, select "Restart the recovery target ", "Executing failover to the recovery target ", or "Execute the final action" as the action to take when an error is detected. However, if the recovery target is inactive, the recovery action is not performed.

The screenshot shows the 'Monitor Resource Properties' dialog box for resource 'mrw1'. The 'Recovery Action' tab is selected. The 'Recovery Action' dropdown is set to 'Executing failover to the recovery target'. The 'Recovery Target' is '[All Groups]' with a 'Browse' button. Below this, there are two unchecked checkboxes: 'Execute migration before Failover' and 'Execute Failover to outside the Server Group'. The 'Final Action' dropdown is set to 'No operation'. At the bottom, there is an unchecked checkbox for 'Execute Script before Recovery Action', a 'Script Settings' button, and 'OK', 'Cancel', and 'Apply' buttons.

Monitor Resource Properties   mrw1	
Info	Monitor(common) Monitor(special) Recovery Action
Recovery Action	Executing failover to the recovery target
Recovery Target *	[All Groups] Browse
Execute migration before Failover	<input type="checkbox"/>
Execute Failover to outside the Server Group	<input type="checkbox"/>
Final Action	No operation
Execute Script before Recovery Action	<input type="checkbox"/>
Script Settings	
OK Cancel Apply	

### Recovery Action

Select the action to take when a monitor error is detected.

- Executing the recovery script  
Execute the recovery script when a monitor error is detected.
- Executing failover to the recovery target  
Perform failover for the group selected as the recovery target or the group to which the group resource selected as the recovery target belongs when a monitor error is detected.
- Restart the recovery target  
Restart the group or group resource selected as the recovery target when a monitor error is detected.
- Execute the final action  
Execute the selected final action when a monitor error is detected.

#### **Execute Failover to outside the Server Group**

Can be configured only for message receive monitor resources. Specify whether to fail over to a server group other than the active server group upon the reception of an error message.

#### **Execute Script before Recovery Action**

Executes the script before the operation performed upon error detection selected as the recovery action.

- When the check box is selected  
A script/command is executed before reactivation. To configure the script/command setting, click Settings.
- When the check box is not selected  
Any script/command is not executed.

\* For details on settings other than those above, see "[Recovery Action tab](#)".

## 4.20 Understanding VM monitor resources

VM monitor resources check whether the virtual machine is alive.

### 4.20.1 Notes on VM monitor resources

- This resource is automatically registered when a virtual machine resource is added.
- For the supported virtual infrastructure versions, see "Operation Environment of VM resources" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".
- The times counter of the recovery action kept by the monitor resource is not reset even though the virtual machine monitor resource recovery is detected while recovery action is in transit, or after all the recovery action have completed. Execute either one of the following procedures when you want to reset the times counter of the recovery action.
  - Reset the times counter of the recovery action by the `clpmonctrl` command.
  - Execute cluster stop/start with the `clpcl` command or Cluster WebUI.

### 4.20.2 Monitoring by VM monitor resources

VM monitor resources monitor the following:

#### **If the virtual machine type is vSphere**

VM monitor resources monitor the virtual machine by using the VMware vSphere API.

An error is detected if the monitoring result is one of the following:

1. The VM status is POWEROFF, SHUTDOWN, or SUSPENDED.
2. Acquiring the VM status failed.

#### **If the virtual machine type is Xenserver**

VM monitor resources monitor the virtual machine by using a general-purpose virtualization library.

An error is detected if the monitoring result is one of the following:

1. The VM status is HALTED, PAUSED, or SUSPENDED.
2. Acquiring the VM status failed.

#### **If the virtual machine type is Kvm**

VM monitor resources monitor the virtual machine by using a general-purpose virtualization library.

An error is detected if the monitoring result is one of the following:

1. The VM status is BLOCKED, SHUTDOWN, PAUSED, SHUTOFF, CRASHED, or NOSTATE.
2. Acquiring the VM status failed.

### 4.20.3 Monitor (special) tab

The screenshot shows a dialog box titled "Monitor Resource Properties | vmw1" with a close button "vmw X". Inside the dialog, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Under this tab, there are two fields: "Virtual Machine Resource\*" with a dropdown menu showing "vm1", and "Wait Time When External Migration Occurs\*" with a text input field containing "15" and a unit label "sec". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### Wait Time When External Migration Occurs

Specify the time to wait for the completion of the migration.

## 4.21 Understanding Dynamic DNS monitor resources

### 4.21.1 Notes on Dynamic DNS monitor resources

There are no detailed settings for Dynamic DNS monitor resources. These monitor resources are used when using the Dynamic DNS resources in EXPRESSCLUSTER.

- A Dynamic DNS monitor resource is automatically created when a Dynamic DNS resource is added. One Dynamic DNS monitor resource is automatically created for each Dynamic DNS resource.
- Dynamic DNS monitor resources cannot be deleted. They are automatically deleted when the Dynamic DNS resource is deleted.
- Do not change the recovery target.
- Monitoring cannot be paused or resumed using the `clpmonctrl` command or from the Cluster WebUI.
- Dynamic DNS monitor resources periodically register virtual host names with the DDNS server. If the target Dynamic DNS resource is active while the cluster is suspended, the Dynamic DNS monitor resource continues operating.
- The setting of Monitor(common) tab-Retry Count is invalid. When you'd like to delay error detection, please change the setting of Monitor(common) tab-Timeout.

### 4.21.2 Settings for Dynamic DNS monitor resources

Dynamic DNS monitor resources periodically register virtual host names with the DDNS server.

There are no detailed settings for Dynamic DNS monitor resources.

## 4.22 Understanding process name monitor resources

Process name monitor resources monitor the process of specified processes. Process stalls cannot be detected.

### 4.22.1 Notes on process name monitor resources

If there are two or more processes having the name specified for the monitor target, only one process is selected according to the following conditions and is subject to monitoring.

If you set 1 for **Minimum Process Count**, and if there are two or more processes having the process name specified for the monitor target, only one process is selected under the following conditions and is subject to monitoring.

1. When the processes are in a parent-child relationship, the parent process is monitored.
2. When the processes are not in a parent-child relationship, the process having the earliest activation time is monitored.
3. When the processes are not in a parent-child relationship and their activation times are the same, the process having the lowest process ID is monitored.

If monitoring of the number of started processes is performed when there are multiple processes with the same name, specify the process count to be monitored for **Minimum Process Count**. If the number of processes with the same name falls short of the specified minimum count, an error is recognized. You can set 1 to 999 for **Minimum Process Count**. If you set 1, only one process is selected for monitoring.

Up to 1023 bytes can be specified for the monitor target process name. To specify a monitor target process with a name that exceeds 1023 bytes, use a wildcard (such as \*).

If the name of the target process is 1024 bytes or longer, only the first 1023 bytes can be recognized as the process name. If you use a wild card (such as \*) to specify a process name, specify a string containing the first 1024 or fewer bytes.

If the name of the target process is long, the latter part of the process name is omitted and output to the log.

If the name of the target process includes double quotations( "" ) or a comma ( , ), the process name might not be correctly output to an alert message.

Check the monitor target process name which is actually running by ps(1) command, etc, and specify the monitor target process name.

Execution result

# ps -eaf							
UID	PID	PPID	C	STIME	TTY	TIME	CMD
root	1	0	0	Sep12	?	00:00:00	init [5]
:							
root	5314	1	0	Sep12	?	00:00:00	/usr/sbin/acpid
root	5325	1	0	Sep12	?	00:00:00	/usr/sbin/sshd
htt	5481	1	0	Sep12	?	00:00:00	/usr/sbin/htt -
retryonerror	0						
:							

From the above command result, /usr/sbin/htt -retryonerror 0 is specified as monitor target process name in the case of monitoring /usr/sbin/htt.

The process name specified for the name of the target process specifies the target process, using the process arguments as part of the process name. To specify the name of the target process, specify the process name containing the

arguments. To monitor only the process name with the arguments excluded, specify it with the wildcard (\*) using right truncation or partial match excluding the arguments.

## 4.22.2 How process name monitor resources perform monitoring

The process name monitor resource monitors a process having the specified process name. If **Minimum Process Count** is set to 1, the process ID is identified from the process name and the deletion of the process ID is treated as an error. Process stalls cannot be detected.

If **Minimum Process Count** is set to a value greater than 1, the number of processes that have the specified process name are monitored. The number of processes to be monitored is calculated using the process name, and if the number falls below the minimum count, an error is recognized. Process stalls cannot be detected.

## 4.22.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | psw1" with a close button (X) in the top right corner. Below the title bar, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Inside this tab, there are two input fields: "Process Name\*" with the value "crond" and "Minimum Process Count\*" with the value "1". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

### Process Name (within 1023 bytes)

Set the name of the target process. The process name can be obtained by using the `ps(1)` command

Wild cards can be used to specify a process name by using one of the following three patterns. No other wild card pattern is permitted.

[prefix search] <string included in the process name>\*

[suffix search] \*<string included in the process name>

[partial search] \*<string included in the process name>\*

### Minimum Process Count (1 to 999)

Set the process count to be monitored for the monitor target process. If the number of processes having the specified monitor target process name falls short of the set value, an error is recognized.

## 4.23 Understanding BMC monitor resources

This cannot be used.

## 4.24 Understanding DB2 monitor resources

DB2 monitor resource monitors DB2 database that operates on servers.

### 4.24.1 Note on DB2 monitor resources

For the supported versions of DB2, see "Applications supported by monitoring options" of "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

This monitoring resource monitors DB2, using the CLI library of DB2. For this reason, it is required to execute "source *instance user home/sqllib/db2profile*" as root user. Write this in a start script.

To monitor a DB2 database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the DB2 database to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**. Also, set up the DB2 client on the host OS side, where monitor resources run, and register the database on the virtual machine to the database node directory.

If the code page of the database and the one of this monitor resource differ, this monitor resource cannot access to the DB2 database. Set an appropriate character code as necessary.

To check the code page of database, execute "db2 get db cfg for *Database\_name*." For details, see DB2 manual.

If values of database name, instance name, user name and password specified by a parameter differ from the DB2 environment for monitoring, DB2 cannot be monitored. Error message is displayed. Check the environment.

Note that the following points about monitor levels described in the next section "How DB2 monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1". Create the monitor table below in that case.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

Alphanumeric characters and some symbols (such as underscores) can be used to specify a monitor table name.

Use SQL statements (in the following example, the monitor table is named **db2watch**)

```
sql> create table <user_name>.db2watch (num int not null primary key)
```

```
sql> insert into db2watch values(0)
sql> commit
```

### **Use EXPRESSCLUSTER command**

Note that monitor resource settings must be completed beforehand.

```
clp_db2w --createtable -n <DB2_monitor_resource_name>
```

To manually delete a monitor table, execute the following command:

```
clp_db2w --deletetable -n <DB2_monitor_resource_name>
```

## **4.24.2 How DB2 monitor resources perform monitoring**

DB2 monitor resources perform monitoring according to the specified monitor level.

- **Level 1 (monitoring by select)**

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- **Level 2 (monitoring by update/select)**

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- **Level 3 (create/drop table each time)**

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

### 4.24.3 Monitor (special) tab

Monitor Resource Properties | db2w1

OK Cancel Apply

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- **Level 1 (monitoring by select)**  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- **Level 2 (monitoring by update/select)**  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- **Level 3 (create/drop table each time)**  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

#### Database Name (Within 255 bytes)

Specify the database to be monitored. You must specify the database.

Default value: None

#### Instance (Within 255 bytes)

Specify the instance name of the database to be monitored. You must specify the instance name.

Default value: db2inst1

#### User Name (Within 255 bytes)

Specify the user name to log on to the database. You must specify the user name.

Specify the DB2 user who can access the specified database.

Default value: db2inst1

**Password** (Within 255 bytes)

Specify the password to log on to the database. You must specify the password.

Default value: None

**Table** (Within 255 bytes)

Specify the name of a monitor table created on the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Be sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database specifications.

Default value: db2watch

**Character Set**

Specify the character set of DB2. You must specify the character code.

Default value: None

**Library Path** (Within 1023 bytes)

Specify the home path to DB2. You must specify the path.

Default value: /opt/ibm/db2/V11.1/lib64/libdb2.so

## 4.25 Understanding FTP monitor resources

FTP monitor resources monitor FTP services that run on the server. FTP monitor resources monitor FTP protocol and they are not intended for monitoring specific applications. FTP monitor resources monitor various applications that use FTP protocol.

### 4.25.1 FTP monitor resources

For monitoring target resources, specify EXEC resources etc. that start FTP. Monitoring starts after a target resource is activated. However, if FTP cannot be started immediately after target resource is activated, adjust the time using **Wait Time to Start Monitoring**.

To monitor an FTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the FTP server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

FTP service may produce operation logs for each monitoring. Configure FTP settings if this needs to be adjusted.

If a change is made to a default FTP message (such as a banner or welcome message) on the FTP server, it may be handled as an error.

### 4.25.2 Monitoring by FTP monitor resources

FTP monitor resources connect to the FTP server and execute the command for acquiring the file list. As a result of monitoring, the following is considered as an error:

1. When connection to the FTP service fails.
2. When an error is notified as a response to the FTP command.

### 4.25.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | ftpw1" with a close button (x) in the top right corner. Below the title bar, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. The main area of the dialog contains four input fields: "IP Address\*" with the value "127.0.0.1", "Port Number\*" with the value "21", "User Name" (empty), and "Password" (masked with grey dots). To the right of the "Password" field is a "Change" button. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

#### IP Address (Within 79 bytes )

Specify the IP address of the FTP server to be monitored. You must specify this IP address. If it is multi-directional standby server, specify FIP.

Usually, specify the loopback address (127.0.0.1) to connect to the FTP server that runs on the local server. If the addresses for which connection is possible are limited by FTP server settings, specify an address

for which connection is possible (such as a floating IP address). To monitor an FTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port Number** (1-65535)

Specify the FTP port number to be monitored. You must specify a port number.

Default value: 21

**User Name** (Within 255 bytes)

Specify the user name to log on to FTP.

Default value: None

**Password** (Within 255 bytes)

Specify the password to log on to FTP.

Default value: None

## 4.26 Understanding HTTP monitor resources

HTTP monitor resource monitors HTTP daemon that operates on servers.

### 4.26.1 Note on HTTP monitor resources

For the supported versions of HTTP, see the "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

To monitor an HTTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the HTTP server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

HTTP monitor resource does not support the client authentication and DIGEST authentication..

### 4.26.2 How HTTP monitor resources perform monitoring

HTTP monitor resource monitors the following:

Monitors the HTTP daemon by connecting to the HTTP daemon on the server and issuing a HTTP request.

This monitor resource determines the following results as an error:

1. an error is notified during the connection to the HTTP daemon.
2. the response message to the HTTP request is not started with "/HTTP"
3. the status code for the response to the HTTP request is in 400s and 500s (when URI other than the default is specified to the request URI)

### 4.26.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | httpw1" with a close button labeled "httpw x". The window has four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is selected. It contains the following fields and controls:

- Connecting Destination\***: A text box containing "localhost".
- Port\***: A text box containing "80".
- Request URI**: An empty text box.
- Protocol**: Radio buttons for "HTTP" (selected) and "HTTPS".
- Request Type**: Radio buttons for "HEAD" (selected) and "GET".
- User Name**: An empty text box.
- Password**: A masked text box (grayed out) with a "Change" button next to it.
- At the bottom right are three buttons: "OK", "Cancel", and "Apply".

**Connecting Destination** (Within 255 bytes)

Specify the HTTP server name to be monitored. You must specify the name.

Usually, specify the loopback address (127.0.0.1) to connect to the HTTP server that runs on the local server. If the addresses for which connection is possible are limited by HTTP server settings, specify an address for which connection is possible (such as a floating IP address). To monitor an HTTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: localhost

**Port** (1 to 65535)

Specify the port number used for connecting the HTTP server. You must specify the number.

Default value: 80 (HTTP)

443 (HTTPS)

**Request URI** (Within 255 bytes)

Set the request URI (for example: "/index.html").

Default value: None

**Protocol**

Configure protocol used for communication with and HTTP server.. In general, HTTP is selected. If you need to connect with HTTP over SSL, select HTTPS.

Default value: HTTP

---

**Note:** OpenSSL is required to use HTTPS.

---

**Request Type**

Specify a type of HTTP request for accessing the HTTP server. Setting this parameter is mandatory.

Default value: HEAD

**User Name** (Within 255 bytes)

Set a user name to login to HTTP

This field is used only in case that you use BASIC authentication.

Default value: None

**Password** (Within 255 bytes)

Set a password to login to HTTP

This field is used only in case that you use BASIC authentication.

Default value: None

## 4.27 Understanding IMAP4 monitor resources

IMAP4 monitor resources monitor IMAP4 services that run on the server. IMAP4 monitor resources monitor IMAP4 protocol but they are not intended for monitoring specific applications. IMAP4 monitor resources monitor various applications that use IMAP4 protocol.

### 4.27.1 Note on IMAP4 monitor resources

For monitoring target resources, specify EXEC resources that start IMAP4 servers. Monitoring starts after a target resource is activated. However, if IMAP4 servers cannot be started immediately after a target resource is activated, adjust the time using **Wait Time to Start Monitoring**.

To monitor an IMAP4 server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the IMAP4 server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

IMAP4 servers may produce operation logs for each monitoring. Configure IMAP4 server settings if this needs to be adjusted.

### 4.27.2 Monitoring by IMAP4 monitor resources

IMAP4 monitor resources connect to the IMAP4 server and execute the command to verify the operation. As a result of monitoring, the following is considered as an error:

1. When connection to the IMAP4 server fails.
2. When an error is notified as a response to the command.

### 4.27.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | imap4w1" with a close button "imap4w X". It contains four tabs: "Info", "Monitor(common)", "Monitor(special)" (which is active), and "Recovery Action". The "Monitor(special)" tab has the following fields and controls:

- IP Address\***: A text box containing "127.0.0.1".
- Port Number\***: A text box containing "143".
- User Name**: An empty text box.
- Password**: A masked text box (gray) with a "Change" button to its right.
- Authentication Method**: Two radio buttons, "AUTHENTICATE LOGIN" (selected) and "LOGIN".
- At the bottom right are three buttons: "OK", "Cancel", and "Apply".

#### IP Address (Within 79 bytes )

Specify the IP address of the IMAP4 server to be monitored. You must specify this IP address. If it is multi-directional standby server, specify FIP.

Usually, specify the loopback address (127.0.0.1) to connect to the IMAP4 server that runs on the local server. If the addresses for which connection is possible are limited by IMAP4 server settings, specify

an address for which connection is possible (such as a floating IP address). To monitor an IMAP4 server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port Number** (1-65535)

Specify the port number of the IMAP4 to be monitored. You must specify this port number.

Default value: 143

**User Name** (Within 255 bytes)

Specify the user name to log on to IMAP4.

Default value: None

**Password** (Within 189 bytes)

Specify the password to log on to IMAP4. Default value: None

**Authentication Method**

Select the authentication method to log on to IMAP4. It must follow the settings of IMAP4 being used:

- **AUTHENTICATE LOGIN** (Default value)  
The encryption authentication method that uses the AUTHENTICATE LOGIN command.
- **LOGIN**  
The plaintext method that uses the LOGIN command.

## 4.28 Understanding MySQL monitor resources

MySQL monitor resource monitors MySQL database that operates on servers.

### 4.28.1 Note on MySQL monitor resources

For the supported versions of MySQL, see the "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

This monitor resource monitors MySQL using the libmysqlclient library of MySQL.

If this monitor resource fails, check that "libmysqlclient.so.xx" exists in the installation directory of the MySQL library.

To monitor a MySQL database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the MySQL database to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

If a value specified by a parameter differs from the MySQL environment for monitoring, an error message is displayed on the Cluster WebUI Alert logs. Check the environment.

Note that the following points about monitor levels described in the next section "How MySQL monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1". Create the monitor table below in that case.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

**Use SQL statements (in the following example, the monitor table is named mysqlwatch)**

```
sql> create table mysqlwatch (num int not null primary key) ENGINE=<engine>;
sql> insert into mysqlwatch values(0);
sql> commit;
```

**Use EXPRESSCLUSTER commands**

Note that monitor resource settings must be completed beforehand.

```
clp_mysqlw --createtable -n <MySQL_monitor_resource_name>
```

To manually delete a monitor table, execute the following command:

```
clp_mysqlw --deletetable -n <MySQL_monitor_resource_name>
```

## 4.28.2 How MySQL monitor resources perform monitoring

MySQL monitor resources perform monitoring according to the specified monitor level.

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

### 4.28.3 Monitor (special) tab

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- **Level 1 (monitoring by select)**  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- **Level 2 (monitoring by update/select)**  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- **Level 3 (create/drop table each time)**  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

#### Database Name (Within 255 bytes)

Specify the database name to be monitored. You must specify the name.

Default value: None

#### IP Address (Within 79 bytes)

Specify the IP address of the server to connect. You must specify the IP address.

Usually, specify the loopback address (127.0.0.1) to connect to the MySQL server that runs on the local server. To monitor a MySQL database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port 1 to 65535**

Specify the port number used for connection. You must specify the port number.

Default value: 3306

**User Name** (Within 255 bytes)

Specify the user name to log on to the database. You must specify the name.

Specify the MySQL user who can access the specified database.

Default value: None

**Password** (Within 255 bytes)

Specify the password to log on to the database.

Default value: None

**Table** (Within 255 bytes)

Specify the name of a monitor table created in the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Make sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database.

Default value: mysqlwatch

**Storage Engine**

Specify the storage engine of MySQL. You must specify the storage engine.

Default value: InnoDB

**Library Path** (Within 1023 bytes)

Specify the home path to MySQL. You must specify the path.

Default value: /usr/lib64/mysql/libmysqlclient.so.20

## 4.29 Understanding NFS monitor resources

NFS monitor resource monitors NFS file server that operates on servers.

### 4.29.1 System requirements for NFS monitor resource

The use of NFS monitor resources requires that the following already be started:

< For Red Hat Enterprise Linux 6, 7 >

- nfs
- rpcbind
- nfslock (unnecessary for NFS v4)

### 4.29.2 Note on NFS monitor resources

For the supported versions of NFS, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

Specify the exports file for the shared directory to be monitored to enable the connection from a local server.

To monitor an NFS file server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the NFS file server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

It is handled as an error that the deletion of nfsd with the version specified for **NFS version** of the **Monitor(special)** tab and mountd corresponding the nfsd is detected. The correspondence between nfsd versions and mountd versions is as follows.

nfsd version	mountd version
v2 (udp)	v1 (tcp) or v2 (tcp)
v3 (udp)	v3 (tcp)
v4 (tcp)	-

### 4.29.3 How NFS monitor resources perform monitoring

NFS monitor resource monitors the following:

Connect to the NFS server and run NFS test command.

This monitor resource determines the following result as an error:

1. Response to the NFS service request is invalid
2. mountd is deleted (excluding NFS v4)
3. nfsd is deleted
4. The rpcbind service is stopped
5. The export area is deleted(unnecessary for NFS v4)

When an error is repeated the number of times set to retry count, it is considered as NFS error.

#### 4.29.4 Monitor (special) tab

Monitor Resource Properties | nfsw1

nfsw ✕

Info Monitor(common) Monitor(special) Recovery Action

Share Directory\* /usr/local/tomcat

NFS Server\* 127.0.0.1

NFS Version\* v4 ▼

OK Cancel Apply

##### Share Directory (Within 1023 bytes)

Specify a directory for sharing files. You must specify the directory.

Default value: None

##### NFS Server (Within 255 bytes)

Specify an IP address of the server that monitors NFS. You must specify the IP address.

Usually, specify the loopback address (127.0.0.1) to connect to the NFS file server that runs on the local server. To monitor an NFS file server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

##### NFS Version

Select one NFS version for NFS monitoring, from the following choices. Be careful to set this NFS version.

For RHEL 7, the NFS version v2 is not supported.

- v2  
Monitors NFS version v2.
- v3  
Monitors NFS version v3.
- v4  
Monitors NFS version v4.

Default value: v4

## 4.30 Understanding ODBC monitor resources

ODBC monitor resource monitors ODBC database that operates on servers.

### 4.30.1 Note on ODBC monitor resources

Since unixODBC Driver Manager is used for the monitoring process, installation of ODBC driver for the database to be monitored and settings for the data source on `odbc.ini` in advance.

To monitor a ODBC database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the ODBC database to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

If a value specified by a parameter differs from the ODBC environment for monitoring, an error message is displayed on the Cluster WebUI Alert logs. Check the environment.

Note that the following points about monitor levels described in the next section "How ODBC monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1". Note that monitor resource settings must be completed beforehand.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

#### Use SQL statements (in the following example, the monitor table is named `odbcwatch`)

```
sql> create table odbcwatch (num int not null primary key) ENGINE=<engine>;
sql> insert into odbcwatch values(0);
sql> commit;
```

#### Use EXPRESSCLUSTER commands

Note that monitor resource settings must be completed beforehand.

```
clp_odbcw --createtable -n <ODBC_monitor_resource_name>
```

To manually delete a monitor table, execute the following command:

```
clp_odbcw --deletetable -n <ODBC_monitor_resource_name>
```

### 4.30.2 How ODBC monitor resources perform monitoring

ODBC monitor resources perform monitoring according to the specified monitor level.

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

### 4.30.3 Monitor (special) tab

**Monitor Table Name\*** odbcwatch

**Message Character Set\*** UTF-8 ▼

OK Cancel Apply

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

**Data Source Name** (Within 255 bytes)

Specify the data source name to be monitored. You must specify the name.

Default value: None

**User Name** (Within 255 bytes)

Specify the user name to log on to the database.

If you have specified user name in odbc.ini, you do not need to specify it.

Default value: None

**Password** (Within 255 bytes)

Specify the password to log on to the database.

Default value: None

**Monitor Table Name** (Within 255 bytes)

Specify the name of a monitor table created in the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Make sure to set the name different from the reserved word in SQL statements.

Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database.

Default value: odbwatch

**Message Character Set**

Specify the character code of database messages.

Default value: UTF-8

## 4.31 Understanding Oracle monitor resources

Oracle monitor resource monitors Oracle database that operates on servers.

### 4.31.1 Note on Oracle monitor resources

For the supported versions of Oracle, see " Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide."

This monitor resource monitors Oracle with the Oracle interface (Oracle Call Interface). For this reason, the library for interface (libclntsh.so) needs to be installed on the server for monitoring.

To monitor an Oracle database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the Oracle database to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**. Also, set up the Oracle client on the host OS side, where monitor resources run, and specify the connection string for connecting to the Oracle database on the virtual machine.

If values of a connection string, user name and password specified by a parameter are different from the Oracle environment for monitoring, Oracle monitoring cannot be done. Error message is displayed. Check the environment.

For the user specified with the user name parameter, the default is sys, but when a monitoring-dedicated user has been configured, for each monitor level the following access permissions must be provided for that user (if the sysdba permission is not provided):

Monitor level	Necessary permissions
Level 0 (database status)	SELECT permission for V\$INSTANCE
Level 1 (monitoring by select)	SELECT permission for a monitor table
Level 2 (monitoring by update/select)	CREATE TABLE / DROP ANY TABLE / INSERT permission for a monitor table / UPDATE permission for a monitor table / SELECT permission for a monitor table
Level 3 (create/drop table each time)	CREATE TABLE / DROP ANY TABLE / INSERT permission for a monitor table / UPDATE permission for a monitor table / SELECT permission for a monitor table

If the administrator user authentication method is only the OS authentication by setting "NONE" to "REMOTE\_LOGIN\_PASSWORDFILE" in the initialization parameter file, specify a database user without SYSDBA authority for the user name of the parameter.

When specifying a database user with SYSDBA authority, an error occurs when this monitor resource starts, causing the monitoring process not to be executed.

If sys is specified for the user name, an Oracle audit log may be output. If you do not want to output large audit logs, specify a user name other than sys.

Use the character set supported by OS when creating a database. If Japanese is set to NLS\_LANGUAGE in the Oracle initialization parameter file, specify English by NLS\_LANG (environment variable of Oracle.) Specify the character set corresponds to the database.

Select the language displayed in the EXPRESSCLUSTER Cluster WebUI Alert logs and OS messages (syslog) for the character code of the monitor resource if an error message is generated from Oracle..

However, as for an error of when connecting to the database such as incorrect user name and alert message may not

be displayed correctly.

For the NLS parameter and NLS\_LANG settings, see the *Globalization Support Guide* by Oracle Corporation.

The character code settings have no effect on the operation of Oracle.

Note that the following points about monitor levels described in the next section "How Oracle monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1". Create the monitor table below in that case.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

Level 3 monitoring needs more performance power than Level 1 and Level 2 as the table is created/dropped each time. Since also the usage of Oracle resources increases continuously, if you do not restart Oracle instances regularly in the operation, Level 3 monitoring is not recommended.

Selectable monitor level	Prior creation of a monitor table
Level 0 (database status)	Optional
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

**When creating by SQL statements (in the following example, the monitor table is named orawatch)**

```
sql> create table orawatch (num number(11,0) primary key);
sql> insert into orawatch values(0);
sql> commit;
```

\*Create this in a schema for the user specified with the user name parameter.

**When using EXPRESSCLUSTER commands**

Note that monitor resource settings must be completed beforehand.

```
clp_oraclew --createtable -n <Oracle monitor resource name>
```

\*When the user other than sys is specified for the user name parameter and the sysdba permission is not provided for that user, CREATE TABLE permission is required for that user.

When deleting the created monitor table manually, run the following command:

```
clp_oraclew --deletetable -n <Oracle monitor resource name>
```

### 4.31.2 How Oracle monitor resources perform monitoring

Oracle monitor resources perform monitoring according to the specified monitor level.

- Level 0 (database status)

The Oracle management table (V\$INSTANCE table) is referenced to check the DB status (instance status).

This level corresponds to simplified monitoring without SQL statements being executed for the monitor table.

An error is recognized if:

1. The Oracle management table (V\$INSTANCE table) status is in the inactive state (MOUNTED,STARTED)
2. The Oracle management table (V\$INSTANCE table) database\_status is in the inactive state (SUSPENDED,INSTANCE RECOVERY)

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 11 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 11 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

### 4.31.3 Monitor (special) tab

Monitor Resource Properties | oraclew1 oraclew X

Info Monitor(common) **Monitor(special)** Recovery Action

**Monitor Type\*** listener and instance monitor ▼

**Monitor Level\*** Level 2 (monitoring by update/select) ▼

**ORACLE\_HOME**

**Character Set\*** AMERICAN\_AMERICA.UTF8 ▼

**Library Path\*** /u01/app/oracle/product/12.2.0/dbhome\_1/lib/libclntsh.so.12.1 ▼

**Collect detailed application information at failure occurrence** ☐

**Collection Timeout** 600 sec

**Set error during Oracle initialization or shutdown** ☐

OK Cancel Apply

#### Monitor Type

Select the Oracle features to be monitored.

- **Monitor Listener and Instance (default)**  
According to the specified monitor level, database connection, reference, and update operations are monitored.
- **Monitor Listener only**  
To check for the listener operation, use the `tnsping` Oracle command. For a monitor resource properties, `ORACLE_HOME` must be set.  
  
If `ORACLE_HOME` is not set, only connection operations for the items specified in the connect string are monitored. Use this to attempt recovery by restarting the Listener service upon a connection error.  
  
Selecting this setting causes the monitor level setting to be ignored.
- **Monitor Instance only**  
A direct (BEQ) connection to the database is established, bypassing the listener and, according to the specified monitor level, database connection, reference, and update operations are monitored. For a monitor resource properties, `ORACLE_HOME` must be set. This is used for direct instance monitoring and recovery action setting without routing through the listener.

When the monitoring target is a database that has an Oracle12c multi-tenant configuration, monitoring using BEQ connection cannot be performed.

If ORACLE\_HOME is not set, only the connection specified with the connect string is established, and any error in the connection operation is ignored. This is used to set the recovery action for a non-connection error together with an Oracle monitor resource for which **Monitor Listener only** is specified.

### Monitor Level

Select one of the following levels. When the monitor type is set to **Monitor Listener only**, the monitor level setting is ignored.

- Level 0 (database status)  
The Oracle management table (V\$INSTANCE table) is referenced to check the DB status (instance status). This level corresponds to simplified monitoring without SQL statements being executed for the monitor table.
- Level 1 (monitoring by select)  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- Level 2 (monitoring by update/select)  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.  
  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- Level 3 (create/drop table each time)  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

### Connect Command (Within 255 bytes)

Specify the connect string for the database to be monitored. You must specify the connect string.

When **Monitor Type** is set to **Monitor Instance only**, set ORACLE\_SID.

Monitor Type	ORACLE_HOME	Connect Command	Monitor Level
Monitor Listener and Instance	Need not be specified	Specify the connect string	As specified
Monitor Listener only	Monitoring dependent on Oracle command if specified	Specify the connect string	Ignored
	Check for connection to the instance through the listener if not specified	Specify the connect string	Ignored
Monitor Instance only	Check for the instance by BEQ connection if specified	Specify ORACLE_SID	As specified
	Check for the instance through the listener if not specified	Specify the connect string	As specified

Default value: None for the connect string

### User Name (Within 255 bytes)

Specify the user name to log on to the database. You must specify the name.

Specify the Oracle user who can access the specified database.

Default value: sys

**Password** (Within 255 bytes)

Specify the password to log on to the database.

Default value: None

**Authority Method**

Specify the database user authentication.

Default value: SYSDBA

**Table** (Within 255 bytes)

Specify the name of a monitor table created on the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Be sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database.

Default value: orawatch

**ORACLE\_HOME** (Within 255 bytes)

Specify the path name configured in ORACLE\_HOME. Begin with [/]. This is used when **Monitor Type** is set to **Monitor Listener only** or **Monitor Instance only**.

Default: None

**Character Set**

Specify the character set of Oracle. You must specify the character code.

Default value: None

**Library Path** (Within 1023 bytes)

Specify the library path of Oracle Call Interface (OCI). You must specify the path.

Default value: /u01/app/oracle/product/12.2.0/dbhome\_1/lib/libclntsh.so.12.1

**Collect detailed application information at failure occurrence**

In case that this function is enabled, when Oracle monitor resource detects errors, the detailed Oracle information is collected. The collected information is written to the /opt/nec/clusterpro/work/rm/ "monitor\_resource\_name"/errinfo.cur folder. When the information is obtained more than once, the existing folders are renamed errinfo.1, errinfo.2, and so on. The detailed Oracle information is collected up to 5 times.

---

**Note:** In case of stopping the Oracle service while collecting the information due to the cluster stop, correct information may not be collected.

---

Default value: disabled

**Collection Timeout**

Specify the timeout value for collecting detailed information.

Default value: 600

**Set error during Oracle initialization or shutdown**

If this function is enabled, a monitor error occurs immediately when Oracle initialization or shutdown in progress is detected.

Disable this function when Oracle is automatically restarted during operation in cooperation with Oracle Clusterware or the like. Monitoring becomes normal even during Oracle initialization or shutdown.

However, a monitor error occurs if Oracle initialization or shutdown continues for one hour or more.

Default value: Disabled

## 4.32 Understanding Oracle Clusterware Synchronization Management monitor resources

It can't be used.

## 4.33 Understanding POP3 monitor resources

POP3 monitor resources monitor POP3 services that run on the server. POP3 monitor resources monitor POP3 protocol but they are not intended for monitoring specific applications. POP3 monitor resources monitor various applications that use POP3 protocol.

### 4.33.1 Note on POP3 monitor resources

For monitoring target resources, specify EXEC resources etc. that start POP3 services. Monitoring starts after target resource is activated. However, if POP3 services cannot be started immediately after target resource is activated, adjust the time using **Wait Time to Start Monitoring**.

To monitor a POP3 server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the POP3 server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

POP3 services may produce operation logs for each monitoring. Configure the POP3 settings if this needs to be adjusted.

### 4.33.2 Monitoring by POP3 monitor resources

POP3 monitor resources connect to the POP3 server and execute the command to verify the operation. As a result of monitoring, the following is considered as an error:

1. When connection to the POP3 server fails.
2. When an error is notified as a response to the command.

### 4.33.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | pop3w1". It has four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is selected. The form contains the following fields and controls:

- IP Address\***: A text box containing "127.0.0.1".
- Port Number\***: A text box containing "110".
- User Name**: A text box.
- Password**: A text box with a "Change" button to its right.
- Authentication Method**: Two radio buttons, "APOP" (selected) and "USER/PASS".
- At the bottom right are three buttons: "OK", "Cancel", and "Apply".

#### IP Address (Within 79 bytes )

Specify the IP address of the POP3 server to be monitored. You must specify this IP address. If it is multi-directional standby server, specify FIP.

Usually, specify the loopback address (127.0.0.1) to connect to the POP3 server that runs on the local server. If the addresses for which connection is possible are limited by POP3 server settings, specify an

address for which connection is possible (such as a floating IP address). To monitor a POP3 server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port Number** (1-65535)

Specify the POP3 port number to be monitored. You must specify this port number.

Default value: 110

**User Name** (Within 255 bytes)

Specify the user name to log on to POP3.

Default value: None

**Password** (Within 255 bytes)

Specify the password to log on to POP3.

Default value: None

**Authentication Method**

Select the authentication method to log on to POP3. It must follow the settings of POP3 being used:

- APOP (Default value)  
The encryption authentication method that uses the APOP command.
- USER/PASS  
The plain text method that uses the USER/PASS command.

## 4.34 Understanding PostgreSQL monitor resources

PostgreSQL monitor resource monitors PostgreSQL database that operates on servers.

### 4.34.1 Note on PostgreSQL monitor resources

For the supported versions of PostgreSQL, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

This monitor resource uses the libpq library of PostgreSQL to monitor PostgreSQL.

If this monitor resource fails, set the application library path to the path where the libpq library of PostgreSQL exists.

To monitor a PostgreSQL database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the PostgreSQL database to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

If a value specified by a parameter differs from the PostgreSQL environment for monitoring, a message indicating an error is displayed on the Alert logs of the Cluster WebUI. Check the environment.

For client authentication, on this monitor resource, the following authentication methods that can be set to the "pg\_hba.conf" file has been checked its operation.

trust, md5, password

When this monitor resource is used, messages like those shown below are output to a log on the PostgreSQL side. These messages are output by the monitor processing and do not indicate any problems.

```
YYYY-MM-DD hh:mm:ss JST moodle moodle LOG: statement: DROP TABLE psqlwatch
YYYY-MM-DD hh:mm:ss JST moodle moodle ERROR: table "psqlwatch" does not exist
YYYY-MM-DD hh:mm:ss JST moodle moodle STATEMENT: DROP TABLE psqlwatch
YYYY-MM-DD hh:mm:ss JST moodle moodle LOG: statement: CREATE TABLE psqlwatch (num_
↪INTEGER NOT NULL PRIMARY KEY)
YYYY-MM-DD hh:mm:ss JST moodle moodle NOTICE: CREATE TABLE / PRIMARY KEY will create_
↪implicit index "psqlwatch_pkey" for table "psql watch"
YYYY-MM-DD hh:mm:ss JST moodle moodle LOG: statement: DROP TABLE psqlwatch
```

Note that the following points about monitor levels described in the next section "How PostgreSQL monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1". Create the monitor table below in that case.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

**Use SQL statements (in the following example, the monitor table is named psqlwatch)**

```
sql> CREATE TABLE psqlwatch ( num INTEGER NOT NULL PRIMARY KEY);  
sql> INSERT INTO psqlwatch VALUES(0) ;  
sql> COMMIT;
```

**Use EXPRESSCLUSTER commands**

Note that monitor resource settings must be completed beforehand.

```
clp_psqlw --createtable -n <PostgreSQL_monitor_resource_name>
```

To manually delete a monitor table, execute the following command:

```
clp_psqlw --deletetable -n <PostgreSQL_monitor_resource_name>
```

## 4.34.2 How PostgreSQL monitor resources perform monitoring

PostgreSQL monitor resources perform monitoring according to the specified monitor level.

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select/vacuum) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop / vacuum) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

### 4.34.3 Monitor (special) tab

Monitor Resource Properties | psqlw1

**Set error during PostgreSQL initialization or shutdown** ☒

OK Cancel Apply

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- **Level 1 (monitoring by select)**  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- **Level 2 (monitoring by update/select)**  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select/vacuum) type.  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- **Level 3 (create/drop table each time)**  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop / vacuum) type.  
Default: Level 2 (monitoring by update/select)

#### Database Name (Within 255 bytes)

Specify the database name to be monitored. You must specify the name.

Default value: None

#### IP Address (Within 79 bytes)

Specify the IP address of the server to connect. You must specify the IP address.

Usually, specify the loopback address (127.0.0.1) to connect to the PostgreSQL server that runs on the local server. To monitor a PostgreSQL database that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port** (1 to 65535)

Specify the port number for connection. You must specify the number.

Default value: 5432

**User Name** (Within 255 bytes)

Specify the user name to log on to the database. You must specify the name.

Specify the PostgreSQL user who can access the specified database.

Default value: postgres

**Password** (Within 255 bytes)

Specify the password to log on to the database.

Default value: None

**Table** (Within 255 bytes)

Specify the name of a monitor table created in the database. You must specify the table name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Be sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database specifications.

Default value: psqlwatch

**Library Path** (Within 1023 bytes)

Specify the home path to PostgreSQL. You must specify the path.

Default value: /opt/PostgreSQL/10/lib/libpq.so.5.10

**Set error during PostgreSQL initialization or shutdown**

When this function is enabled, a monitor error occurs immediately upon the detection of PostgreSQL initialization or shutdown in progress.

When this function is disabled, monitoring becomes normal even during PostgreSQL initialization or shutdown.

However, a monitor error occurs if PostgreSQL initialization or shutdown continues for one hour or more.

Default value: Enabled

## 4.35 Understanding Samba monitor resources

Samba monitor resource monitors samba file server that operates on servers.

### 4.35.1 Note on Samba monitor resources

For the supported versions of samba, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

If this monitor resource fails, the parameter value and samba environment may not match. Check the samba environment

Specify the smb.conf file for the shared name to be monitored to enable a connection from a local server. Allow guest connection when the security parameter of the smb.conf file is "share."

Samba functions except file sharing and print sharing

To monitor a samba file server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the samba file server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

If the smbmount command is run on the monitoring server when the samba authentication mode is "Domain" or "Server," it may be mounted as a user name specified by the parameter of this monitor resource.

### 4.35.2 How Samba monitor resources perform monitoring

From internal version 4.1.0-1, Samba monitor resources use the shared library libsmbclient.so.0.

Samba monitor resource monitors the following:

By connecting to samba server and verify establishment of tree connection to resources of the samba server.

This monitor resource determines the following results as an error:

1. A response to samba service request is invalid.

### 4.35.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | sambaw1" with a close button "sambaw X". It has four tabs: "Info", "Monitor(common)", "Monitor(special)" (which is selected), and "Recovery Action". The "Monitor(special)" tab contains the following fields:

Share Name*	samba
IP Address*	127.0.0.1
Port*	139
User Name*	user1
Password	<input type="password"/> <span>Change</span>

At the bottom right are three buttons: "OK", "Cancel", and "Apply".

Share Name (Within 255 bytes)

Specify the shared name of samba server to be monitored. You must specify the name.

Default value: None

**IP Address** (Within 79 bytes)

Specify the IP address of samba server. You must specify the IP address.

Usually, specify the loopback address (127.0.0.1) to connect to the samba file server that runs on the local server. To monitor a samba file server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

**Port** (1 to 65535)

Specify the port number to be used by samba daemon. You must specify the port number. If the version of libsmbclient is 3 or earlier (e.g. libsmbclient.so provided with RHEL 6), the **Port** field can accept only 139 or 445. Specify the same value for smb ports of the smb.conf as well.

Default value: 139

**User Name** (Within 255 bytes)

Specify the user name to log on to the samba service. You must specify the user name.

Default value: None

**Password** (Within 255 bytes)

Specify the password to log on to the samba service.

Default value: None

## 4.36 Understanding SMTP monitor resources

SMTP monitor resource monitors SMTP daemon that operates on servers.

### 4.36.1 Note on SMTP monitor resources

For the supported versions of SMTP, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

If a state that the load average exceeds the RefuseLA value set in the sendmail.def file for a certain period of time, the monitoring commands may consider this as an error and perform failover.

To monitor an SMTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the VM resource as the monitor target and specify enough wait time for the SMTP server to become accessible after the VM resource is activated for **Wait Time to Start Monitoring**.

### 4.36.2 How SMTP monitor resources perform monitoring

SMTP monitor resource monitors the following:

Monitors the SMTP daemon by connecting to the SMTP daemon on the server and issuing the NOOP command

This monitor resource determines the following result as an error:

1. An error reporting as the response to the SMTP daemon or issued NOOP command.

### 4.36.3 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | smtpw1" with a close button (X) in the top right corner. Below the title bar, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Inside this tab, there are two input fields: "IP Address\*" with the value "127.0.0.1" and "Port Number\*" with the value "25". At the bottom right of the dialog, there are three buttons: "OK", "Cancel", and "Apply".

#### IP Address (Within 79 bytes)

Specify the IP address of the SMTP server to be monitored. You must specify the IP address.

Usually, specify the loopback address (127.0.0.1) to connect to the SMTP server that runs on the local server. To monitor an SMTP server that runs in the guest OS on a virtual machine controlled by a VM resource, specify the IP address of the virtual machine.

Default value: 127.0.0.1

#### Port (1 to 65535)

Specify the port number used to connect to the SMTP server. You must specify the port number.

Default value: 25

## 4.37 Understanding SQL Server monitor resources

SQL Server monitor resource monitors SQL Server database that operates on servers.

### 4.37.1 Note on SQL Server monitor resources

For the supported versions of SQL Server, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

This monitor resource monitors SQL Server using Microsoft ODBC Driver for SQL Server.

If a value specified by a parameter differs from the SQL Server environment for monitoring, an error message is displayed on the Cluster WebUI Alert logs. Check the environment.

If "Level 1" is selected as a monitor level described in the next subsection "How SQL Server monitor resources perform monitoring", monitor tables must be created manually beforehand.

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1".

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 0 (database status)	Optional
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

Alphanumeric characters and some symbols (such as underscores) can be used to specify a monitor table name.

**Use SQL statements (in the following example, the monitor table is named sqlwatch)**

- When SET IMPLICIT\_TRANSACTIONS OFF

```
sql> CREATE TABLE sqlwatch (num INT NOT NULL PRIMARY KEY)
sql> GO
sql> INSERT INTO sqlwatch VALUES(0)
sql> GO
```

- When SET IMPLICIT\_TRANSACTIONS ON

```
sql> CREATE TABLE sqlwatch (num INT NOT NULL PRIMARY KEY)
```

```
sql> GO
sql> INSERT INTO sqlwatch VALUES(0)
sql> GO
sql> COMMIT
sql> GO
```

#### **Use EXPRESSCLUSTER commands**

clp\_sqlserverw --createtable -n <SQL Server\_monitor\_resource\_name>

To manually delete a monitor table, execute the following command:

clp\_sqlserverw --deletetable -n <SQL Server\_monitor\_resource\_name>

### **4.37.2 How SQL Server monitor resources perform monitoring**

SQL Server monitor resources perform monitoring according to the specified monitor level.

- **Level 0 (database status)**

The SQL Server management table is referenced to check the DB status. This level corresponds to simplified monitoring without SQL statements being issued for the monitor table.

An error is recognized if:

1. The database status is not online

- **Level 1 (monitoring by select)**

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- **Level 2 (monitoring by update/select)**

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- **Level 3 (create/drop table each time)**

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- **Level 0 (database status)**  
The SQL Server management table is referenced to check the DB status. This level corresponds to simplified monitoring without SQL statements being executed for the monitor table.
- **Level 1 (monitoring by select)**  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- **Level 2 (monitoring by update/select)**  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- **Level 3 (create/drop table each time)**  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

#### Database Name (Within 255 bytes)

Specify the database name to be monitored. You must specify the name.

Default value: None

#### Server Name (Within 255 bytes)

Specify the database server name to be monitored. You must specify the name.

Default value: localhost

#### User Name (Within 255 bytes)

Specify the user name to log on to the database. You must specify the name.

Specify the SQL Server user who can access the specified database.

Default value: SA

**Password** (Within 255 bytes)

Specify the password to log on to the database. You must specify the password.

Default value: None

**Monitor Table Name** (Within 255 bytes)

Specify the name of a monitor table created in the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Make sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database.

Default value: sqlwatch

**ODBC Driver Name** (Within 255 bytes)

Specify the ODBC driver name of SQL Server. You must specify the name.

Default value: ODBC Driver 13 for SQL Server

## 4.38 Understanding Sybase monitor resources

Sybase monitor resource monitors Sybase database that operates on servers.

### 4.38.1 Note on Sybase monitor resources

For the supported versions of Sybase, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

This monitor resource monitors ASE using Open Client DB-Library/C of ASE. If a value specified by a parameter differs from the ASE environment for monitoring, an error message is displayed on the Cluster WebUI Alert logs. Check the environment .

Note that the following points about monitor levels described in the next section "How Sybase monitor resources perform monitoring".

A monitor error occurs if there is no monitor table at the start of monitoring in "Level 1" Create the monitor table below in that case.

If there is no monitor table at the start of monitoring in "Level 2", EXPRESSCLUSTER automatically creates the monitor table. In this case, a message indicating that the Cluster WebUI Alert logs does not have the monitor table is displayed.

The load on the monitor at "Level 3" is higher than that at "Level 1" and "Level 2" because the monitor in "Level 3" creates or deletes monitor tables for each monitoring.

Selectable monitor level	Prior creation of a monitor table
Level 0 (database status)	Optional
Level 1 (monitoring by select)	Required
Level 2 (monitoring by update/select)	Optional
Level 3 (create/drop table each time)	Optional

Create a monitor table using either of the following methods:

Alphanumeric characters and some symbols (such as underscores) can be used to specify a monitor table name.

#### Use SQL statements (in the following example, the monitor table is named sybwatch)

```
sql> CREATE TABLE sybwatch (num INT NOT NULL PRIMARY KEY)
sql> GO
sql> INSERT INTO sybwatch VALUES(0)
sql> GO
sql> COMMIT
sql> GO
```

#### Use EXPRESSCLUSTER commands

Note that monitor resource settings must be completed beforehand.

```
clp_sybasew --createtable -n <Sybase_monitor_resource_name>
```

To manually delete a monitor table, execute the following command:

```
clp_sybasew --deletetable -n <Sybase_monitor_resource_name>
```

### 4.38.2 How Sybase monitor resources perform monitoring

Sybase monitor resources perform monitoring according to the specified monitor level.

- Level 0 (database status)

The Sybase management table (sys.sysdatabases) is referenced to check the DB status. This level corresponds to simplified monitoring without SQL statements being issued for the monitor table.

An error is recognized if:

1. The database status is in an unusable state, e.g., offline.

- Level 1 (monitoring by select)

Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message

- Level 2 (monitoring by update/select)

Monitoring with reference to and update of the monitoring table. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (update/select) type.

If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

- Level 3 (create/drop table each time)

Creation/deletion of the monitor table by statement as well as update. One SQL statement can read/write numerical data of up to 10 digits. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

An error is recognized if:

1. An error message is sent in response to a database connection or SQL statement message
2. The written data is not the same as the read data

#### Monitor Level

Select one of the following levels. You cannot omit this level setting.

- **Level 0 (database status)**  
The Sybase management table (sys.sysdatabases) is referenced to check the DB status. This level corresponds to simplified monitoring without SQL statements being issued for the monitor table.
- **Level 1 (monitoring by select)**  
Monitoring with only reference to the monitor table. SQL statements executed for the monitor table are of (select) type.
- **Level 2 (monitoring by update/select)**  
Monitoring with reference to and update of the monitoring table. SQL statements executed for the monitor table are of (update/select) type.  
If a monitor table is automatically created at the start of monitoring, the SQL statement (create/insert) is executed for the monitor table.
- **Level 3 (create/drop table each time)**  
Creation/deletion of the monitor table by statement as well as update. SQL statements executed for the monitor table are of (create / insert / select / drop) type.

Default: Level 2 (monitoring by update/select)

#### Database Name (Within 255 bytes)

Specify the database to be monitored. You must specify the database.

Default value: None

#### Database Server Name (Within 255 bytes)

Specify the database server name to be monitored. You must specify the database server.

Default value: None

#### User Name (Within 255 bytes)

Specify the user name to log on to the database. You must specify the user name.

Specify the Sybase user who can access the specified database.

Default value: sa

**Password** (Within 255 bytes)

Specify the password to log on to the database.

Default value: None

**Table** (Within 255 bytes)

Specify the name of a monitor table created in the database. You must specify the name.

Make sure not to specify the same name as the table used for operation because a monitor table will be created and deleted. Make sure to set the name different from the reserved word in SQL statements. Some characters cannot be used to specify a monitor table name according to the database specifications. For details, refer to the database.

Default value: sybwatch

**Library Path** (Within 1023 bytes)

Specify the home path to Sybase. You must specify the path.

Default value: /opt/sap/OCS-16\_0/lib/libsybdb64.so

## 4.39 Understanding Tuxedo monitor resources

Tuxedo monitor resource monitors Tuxedo that operates on servers.

### 4.39.1 Note on Tuxedo monitor resources

For the supported versions of Tuxedo, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

If any library of the Tuxedo such as libtux.so does not exist, monitoring cannot be performed.

### 4.39.2 How Tuxedo monitor resources perform monitoring

Tuxedo monitor resource monitors the following:

This monitor resource executes the application server monitoring by using the API of the Tuxedo. The command determines the following results as an error:

1. An error is reported in response to ping.

### 4.39.3 Monitor (special) tab

Monitor Resource Properties | tuxw1

Info Monitor(common) **Monitor(special)** Recovery Action

Application Server Name\* BBL

Config File\* /home/Oracle/tuxedo/work/

Library Path\* acle/tuxedo/tuxedo12.1.3. v

**Application Server Name** (Within 255 bytes)

Specify the IP address of the server to be monitored. You must specify the name.

Default value: BBL

**Config File** (Within 1023 bytes)

Specify the placement file name of Tuxedo. You must specify the name.

Default value: None

**Library Path** (Within 1023 bytes)

Specify the library path of Tuxedo. You must specify the path.

Default value: /home/Oracle/tuxedo/tuxedo12.1.3.0.0/lib/libtux.so

## 4.40 Understanding WebLogic monitor resources

WebLogic monitor resource monitors WebLogic that operates on servers.

### 4.40.1 Note on WebLogic monitor resources

For the supported versions of WebLogic, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

If the selected monitoring method is WLST for this monitor resource, the monitoring requires a Java environment. Since the Java functions are used by the application server system, a stall of Java (if any) may be recognized as an error.

If WebLogic monitor resources are not available at the startup of WebLogic, they will be judged as being abnormal. Adjust [Wait Time to Start Monitoring], or start WebLogic before the startup of the WebLogic monitor resources (for example, specify the EXEC resource for starting WebLogic as a monitor target resource)

If [RESTful API] is selected as a monitoring method for an RHEL8 environment, specify [HTTP] for a protocol.

### 4.40.2 How WebLogic monitor resources perform monitoring

WebLogic monitor resource monitors the following:

- Monitoring method: if RESTful API is selected

WebLogic offers RESTful APIs called WebLogic RESTful management services.

The RESTful APIs allow you to monitor the application server.

As a result, an error is considered to be found if:

1. There is an error message in response to the RESTful API.

---

**Note:** Compared with the WLST monitoring method, RESTful API can reduce the CPU load of the application server under the monitoring.

---

- Monitoring method: if WLST is selected

Monitors the application server by performing connect with the "weblogic.WLST" command.

This monitor resource determines the following results as an error:

1. An error reporting as the response to the connect.

The operations are as follows, based on **Authentication Method**.

- DemoTrust: SSL authentication method using authentication files for demonstration of WebLogic
- CustomTrust: SSL authentication method using user-created authentication files
- Not Use SSL: SSL authentication method is not used.

**IP Address** (Within 79 bytes)

Specify the IP address of the server to be monitored. You must specify the IP address.

Default value: 127.0.0.1

**Port** (1 to 65535)

Specify the port number used to connect to the server. You must specify the number.

Default value: 7002

**Monitor Method**

Specify the method of monitoring the server. Setting this parameter is mandatory.

Default value: RESTful API

**Protocol**

Specify the protocol of the server to be monitored. Setting this parameter is mandatory if RESTful API is selected in **Monitor Method**.

Default value: HTTP

---

**Note:** Specify HTTP for an RHEL8 environment.

---

**User Name** (Within 255 bytes)

Specify the name of the WebLogic user. Setting this parameter is mandatory if RESTful API is selected in **Monitor Method**.

Default value: weblogic

**Password** (Within 255 bytes)

Specify the password for WebLogic, if necessary, with RESTful API selected in **Monitor Method**.

Default value: None

**Account Shadow**

When you specify a user name and a password directly, select **Off**. If not, select **On**. You must specify the setting.

Default value: Off

**Config File** (Within 1023 bytes)

Specify the file in which the user information is saved. You must specify the file if **Account Shadow** is **On**.

Default value: None

**Key File** (Within 1023 bytes)

Specify the file in which the password required to access to a config file path is saved. Specify the full path of the file. You must specify the file if **Account Shadow** is **On**.

Default value: None

**User Name** (Within 255 bytes)

Specify the user name of WebLogic. You must specify the file if **Account Shadow** is **Off**.

Default value: weblogic

**Password** (Within 255 bytes)

Specify the password of WebLogic.

Default value: None

**Authority Method**

Specify the authentication method when connecting to an application server. You must specify the method.

Specify **DemoTrust** or **Custom Trust** for **Authority Method**, in order to execute monitoring by using the SSL communication.

It is determined whether to use **DemoTrust** or **CustomTrust**, according to the setting of WebLogic Administration Console.

When **Keystores** of WebLogic Administration Console is set to **Demo Identity and Demo Trust**, specify **Demo Trust**. In this case, you do not need to make settings for **Key Store File**.

When **Keystores** of WebLogic Administration Console is set to **Custom Identity and Custom Trust**, specify **Custom Trust**. In this case, you need to make settings for **Key Store File**.

Default value: DemoTrust

**Key Store File** (Within 1023 bytes)

Specify the authentication file when authenticating SSL. You must specify this when the **Authority Method** is **CustomTrust**. Set the file specified in **Custom Identity Key Store File** on WebLogic Administration Console.

Default value: None

**Domain Environment File** (Within 1023 bytes)

Specify the domain environment file name of WebLogic. You must specify the file name.

Default value:

/home/Oracle/product/Oracle\_Home/user\_projects/domains/base\_domain/bin/setDomainEnv.sh

**Add Command Option** (Within 1023 bytes)

Specify the additional command option when changing the option to be passed to the [webLogic.WLST] command.

Default value: -Dwlst.offline.log=disable -Duser.language=en\_US

## 4.41 Understanding WebSphere monitor resources

WebSphere monitor resource monitors WebSphere that operates on servers.

### 4.41.1 Note on WebSphere monitor resources

For the supported versions of WebSphere, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

A Java environment is required to start monitoring with this monitor resource. The application server system uses Java functions. If Java stalls, it may be recognized as an error.

### 4.41.2 How WebSphere monitor resources perform monitoring

WebSphere monitor resource monitors the following:

This monitor resource monitors the following:

Executes monitoring of the application server by using the serverStatus.sh command.

The monitor resource determines the following result as an error:

1. an error is reported with the state of the acquired application server.

### 4.41.3 Monitor (special) tab

The screenshot shows a dialog box titled "Monitor Resource Properties | wasw1" with a close button (X) in the top right corner. The dialog has four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is currently selected. Inside this tab, there are five labeled input fields: "Application Server Name\*" (containing "server1"), "Profile Name\*" (containing "default"), "User Name\*" (containing "user1"), "Password" (a greyed-out field), and "Install Path\*" (containing "/opt/IBM/WebSphere/AppS" with a dropdown arrow). To the right of the "Password" field is a "Change" button. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

**Application Server Name** (Within 255 bytes)

Specify the application server name to be monitored. You must specify the name.

Default value: server1

**Profile Name** (Within 1023 bytes)

Specify the profile name of WebSphere. You must specify the name.

Default value: default

**User Name** (Within 255 bytes)

Specify the user name of WebSphere. You must specify the name.

Default value: None

**Password** (Within 255 bytes)

Specify the password of WebSphere.

Default value: None

**Install Path** (Within 1023 bytes)

Specify the installation path of WebSphere. You must specify the path.

Default value: /opt/IBM/WebSphere/AppServer

## 4.42 Understanding WebOTX monitor resources

WebOTX monitor resource monitors WebOTX that operates on servers.

### 4.42.1 Note on WebOTX monitor resources

For the supported versions of WebOTX, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

A Java environment is required to start monitoring with this monitor resource. The application server system uses Java functions. If Java stalls, it may be recognized as an error.

### 4.42.2 How WebOTX monitor resources perform monitoring

WebOTX monitor resource monitors the following:

This monitor resource monitors the following:

Executes monitoring of the application server by using the otxadmin.sh command.

The monitor resource determines the following result as an error:

1. an error is reported with the state of the acquired application server.

### 4.42.3 Monitor (special) tab

Monitor Resource Properties | obxw1

Info Monitor(common) **Monitor(special)** Recovery Action

Connecting Destination\* localhost

Port Number\* 6212

User Name\* user1

Password  Change

Install Path\* /opt/WebOTX

#### Connecting Destination (Within 255 bytes)

Specify the server name to be monitored. You must specify the name.

Default value: localhost

#### Port (1 to 65535)

Specify the port number used to connect to the server. You must specify the number.

When monitoring a WebOTX user domain, specify the management port number for the WebOTX domain. The management port number is the number which was set for "domain.admin.port" of <domain\_name>.properties when the domain was created. Refer to the WebOTX documents for details of <domain\_name>.properties.

Default value: 6212

**User Name** (Within 255 bytes)

Specify the user name of WebOTX. You must specify the name.

When monitoring a WebOTX user domain, specify the login user name for the WebOTX domain.

Default value: None

**Password** (Within 255 bytes)

Specify the password of WebOTX.

Default value: None

**Install Path** (Within 1023 bytes)

Specify the installation path of WebOTX. You must specify the path.

Default value: /opt/WebOTX

## 4.43 Understanding JVM monitor resources

JVM monitor resources monitor information about the utilization of resources that are used by Java VM or an application server running on a server.

### 4.43.1 Note on JVM monitor resources

The **Java installation path** on the **JVM Monitor** tab of **Cluster Properties** must be set before adding JVM monitor resource.

For a target resource, specify an application server running on Java VM such as WebLogic Server or WebOTX. As soon as the JVM monitor resource has been activated, the Java Resource Agent starts monitoring, but if the target (WebLogic Server or WebOTX) cannot start running immediately after the activation of the JVM monitor resource, use **Wait Time to Start Monitoring** to compensate.

The setting of Monitor(common) tab-Retry Count is invalid. When you'd like to delay error detection, please change the setting of Cluster Properties-JVM monitor Tab-Resource Measurement Settings [Common]-Retry Count.

JBoss monitoring does not support Java 9 or higher.

### 4.43.2 How JVM monitor resources perform monitoring

JVM monitor resource monitors the following:

Monitors application server by using JMX (Java Management Extensions).

The monitor resource determines the following results as errors:

- Target Java VM or application server cannot be connected
- The value of the used amount of resources obtained for the Java VM or application server exceeds the user-specified threshold a specified number of times (error decision threshold) consecutively

As a result of monitoring, an error is regarded as having been solved if:

- The value falls below the threshold when restarting the monitoring after the recovery action.

---

**Note:** Collect Cluster Logs in the Cluster WebUI does not handle the configuration file and log files of the target (WebLogic Server or WebOTX).

---

The following figure illustrates monitoring by a JVM monitor resource.

In phase a), it starts monitoring the target Java VM. For this monitoring, JMX (Java Management Extensions) is used. From the Java VM via JMX, Java Resource Agent periodically obtains data on the resource usage, checking the status of the Java VM.

In phase b), when the status changes from normal to abnormal, the detected error of the Java VM is displayed on Cluster WebUI, where you can see the status and the corresponding alert. In phase c), the failure is reported to syslog and the JVM operation log. If the alert service is used, email notification is also available.

When the status changes from abnormal to normal after phase a), Cluster WebUI is informed in phase d) that the Java VM's returning to normal is detected. In phase e), the restoration is reported to syslog and the JVM operation log.

Fig. 4.72: Flow of monitoring by a JVM monitor resource

The standard operations when the threshold is exceeded are as described below.

In the following figure, the horizontal axis indicates a lapse of time; the vertical axis shows whether the monitoring threshold is exceeded or not.

If a count of consecutively exceeding the threshold reaches a specified value (five in this figure), an error is considered to occur.

After that, when the specified value is reached by a count of consecutively falling short of the threshold, the situation is considered to return to normal.

Fig. 4.73: Behavior when the threshold is exceeded

The operations performed if an error persists are as described below.

If a count of consecutively exceeding the threshold reaches a specified value, an error is considered to occur. After that, even if the consecutive excess reoccurs by the specified count, Cluster WebUI does not alert you to it.

Fig. 4.74: Behavior when an error persists

The following example describes the case of monitoring Full GC (Garbage Collection).

In the following figure, the horizontal axis indicates a lapse of time. The upper part of the figure illustrates whether the GC occurrence is detected at each timing of monitoring; the lower part shows how many times Full GC is consecutively detected at each point of time. If a count of the consecutive Full GC occurrence reaches a specified value, the JVM monitor resource considers it as an error. In this case, the error threshold is set at five. Therefore, when the count reaches five, an error is considered to occur.

Full GC has a significant influence on the system, thus the recommended error threshold is 1 time.

Fig. 4.75: Image of monitoring (when the error threshold is set at five)

### 4.43.3 Linking with the load balancer (health check function)

Target load balancer: Load balancer with health check function for HTML files

JVM monitor resources can link with the load balancer. This section describes an example of linking when WebOTX is used as the application to be monitored. The load balancer linkage provides a health check function and target Java VM load calculation function. To link with the BIG-IP Local Traffic Manager, see "[Linking with the BIG-IP Local Traffic Manager](#)".

Distributed nodes are servers that are subject to load balancing, while the distributed node module is installed in the distributed nodes. The distributed node module is included in InterSec/LB400\*.

To use the function, configure the settings through the Cluster WebUI Cluster Properties - **JVM monitor** tab - **Load Balancer Linkage Settings** dialog box; the health check function of the load balancer is linked.

When a load balancing system is configured with the load balancer on the server, the JVM monitor resource renames the HTML file specified by **HTML File Name** to the name specified by **HTML Renamed File Name** upon the detection of a WebOTX error (for example, exceeding the threshold for collected information).

The JVM monitor resource halts for the wait time, or 20 seconds, after renaming the HTML file. The wait time is intended to prevent WebOTX from being restarted before the load balancer finishes disconnecting the distributed node.

Once the JVM monitor resource detects the normality of WebOTX (e.g., the threshold specified for the collected information is not exceeded after reconnection) after WebOTX rebooting, the HTML file name set with **HTML Renamed File Name** is restored to that specified by **HTML File Name**.

The load balancer periodically health-checks the HTML file, and if a health check fails, the distributed node is determined to be not alive, so that the load balancer disconnects that distributed node. In the case of InterSec/LB400\*, configure the health check interval, health check timeout, and retry count to determine the node down state by the health check with the health check (distributed node) interval parameter, HTTP health check timeout parameter, and health check (distributed node) count parameter, that are accessible from **ManagementConsole** for the load balancer->**LoadBalancer**->**System Information**.

Configure the parameters using the following as a reference.

20-second wait time  $\geq$  (health check (distributed node) interval + HTTP health check timeout) x health check (distributed node) count

- Configuring the health check function of the load balancer to be linked with the JVM monitor resource
  - Health check (distributed node) interval: 10 seconds
  - HTTP health check timeout: 1 second
  - Health check (distributed node) count: 2 times

Fig. 4.76: Health check function of the load balancer to be linked with the JVM monitor resource

#### 4.43.4 Linking with the load balancer (target Java VM load calculation function)

Target load balancer: InterSec/LB400\*

JVM monitor resources can link with the load balancer. This section describes an example of linking when WebOTX is used as the application to be monitored. The load balancer linkage provides a health check function and target Java VM load calculation function. To link with the BIG-IP Local Traffic Manager, see *"Linking with the BIG-IP Local Traffic Manager"*.

Distributed nodes are servers that are subject to load balancing, while the distributed node module is installed in the distributed node. The distributed node module is included in InterSec/LB400\*.

To use this function, the following settings are required. This function works together with the CPU load-dependent weighting function of the load balancer.

- **Properties - Monitor(special) tab -> Tuning properties - Memory dialog box - Monitor Heap Memory Rate - Total Usage**
- **Properties - Monitor(special) tab-> Tuning properties - Load Balancer Linkage dialog box - Memory Pool Monitor**

According to the following steps, first install the distributed node module on each server, and then execute the load balancer linkage setup command `clpjra_lbsetup.sh` to configure the distributed node modules.

---

**Note:** Execute the command from an account having the root privilege.

---

1. Execute "<EXPRESSCLUSTER\_installation\_folder>/ha/jra/bin/clpjra\_lbsetup.sh." The functions of the arguments are as described below.

(Example) `clpjra_lbsetup.sh -e 1 -i 120 -t 180`

Argument	Description	Value
-e	Enables or disables the function.	0 or 1
		0: Disable 1: Enable
-i	Specify the execution interval for the target Java VM load calculation command, in seconds.	1 to 2147483646
-t	Specify the timeout for the target Java VM load calculation command, in seconds.	1 to 2147483646

The JVM monitor resource calculates the load on the target Java VM according to the information obtained about the Java memory. Obtain the Java VM load from the following expression. The threshold is the value obtained by multiplying the entire amount of the Java heap area by the use ratio set with the **Monitor(special) tab - Tuning properties - Memory tab - Monitor Heap Memory Rate - Total Usage**.

Java VM load (%) = current memory usage (MB) x 100/threshold (MB)

For the distributed node module installed on a server on which JVM monitor resource is running, commands are periodically executed to compare the obtained target Java VM load with the CPU load obtained separately, and to notify the load balancer of the higher load value as a CPU load. The load balancer distributes the traffic (requests) to the appropriate servers according to the CPU load of the distributed node.

- Configuring the load calculation function of the distributed node module
  - Command execution interval: the interval that is set with the load balancer linkage setup command

Fig. 4.77: Load calculation function of the distributed node module

#### 4.43.5 Linking with the BIG-IP Local Traffic Manager

Target load balancer: BIG-IP Local Traffic Manager

The JVM monitor resource can link with BIG-IP LTM. Hereafter, the explanation assumes the use of Tomcat as the application server to be monitored. Linkage with BIG-IP LTM offers the distributed node control function and the target Java VM load calculation function.

The linkage between BIG-IP LTM and the JVM monitor resource is realized with the BIG-IP series API (iControl).

The distributed node is the load distribution server, and the linkage module is that which is installed in each distributed node. The linkage module is contained in Java Resource Agent.

To use the distributed node control function, specify the setting with **Cluster WebUI Cluster Properties -> JVM Monitor** tab -> **Load Balancer Linkage Settings** dialog box, **JVM monitor resource Properties - Monitor(special)** tab - **Tuning** properties - **Load Balancer Linkage** tab.

To use the target Java VM load calculation function, specify the setting with **Cluster WebUI Cluster Properties -> JVM Monitor** tab -> **Load Balancer Linkage Settings** dialog box.

The following BIG-IP LTM linkage error message is output to the JVM operation log. For details, see "*JVM monitor resource log output messages*" in "10. Error messages".

```
Error: Failed to operate clpjra_bigip.[error code]
```

If the relevant server configures the BIG-IP LTM load distribution system, when the JVM monitor detects a Tomcat failure (for example: the amount of collection information exceeds the specified threshold), iControl is used to update the BIG-IP LTM distributed node status from "enable" to "disable."

After updating the status of the distributed node of BIG-IP LTM, the JVM monitor waits until the number of connections of the distributed node falls to 0. After waiting, it executes **Restart Command** specified on the JVM monitor resource **Properties - Monitor(special)** tab -> **Tuning** properties - **Load Balancer Linkage** tab. It does not execute the action specified by **Restart Command** if the number of connections of the distributed node does not fall to 0, even if **Timeout** elapses, as specified on the **JVM monitor resource Properties - Monitor(special)** tab -> **Tuning** properties - **Load Balancer Linkage** tab.

When the JVM monitor detects a Tomcat failure recovery, it uses iControl to update the status of the BIG-IP LTM distributed node from "disable" to "enable." In this case, it does not execute the action specified by **Restart Command** specified on the JVM monitor resource **Properties - Monitor(special)** tab -> **Tuning** properties - **Load Balancer Linkage** tab.

If the distributed node status is "disable", BIG-IP LTM determines the distributed node to be down and therefore disconnects it. Use of the distributed node control function requires no related setting for BIG-IP LTM.

The distributed node status is updated by BIG-IP LTM when the JVM monitor detects a failure or failure recovery. Therefore, after the failover generated by an operation other than JVM monitoring, the distributed node status of BIG-IP LTM may be "enable".

Fig. 4.78: Distributed node control function

The JVM monitoring calculates the load on the target Java VM according to the information obtained about the Java memory.

Obtain the Java VM load from the following expression. Java VM load (%) is the value obtained by multiplying the entire amount of the Java heap area by the use ratio set with **Monitor(special)** tab - **Tuning** properties - **Memory** tab - **Monitor Heap Memory Rate** - **Total Usage**.

Java VM load (%) = current memory usage (MB) x 100/threshold (MB)

The linkage module installed on the server on which the JVM monitor runs executes a command at regular intervals, and reports the load collected on the target Java VM to BIG-IP LTM. BIG-IP LTM distributes the traffic (request) to the optimal server according to the load status of Java VM of the distributed node.

Set the following EXPRESSCLUSTER settings with the Cluster WebUI.

- JVM monitor resource

**JVM Monitor Resource Tuning Properties**

Memory Thread GC WebLogic **Load Balancer Linkage**

**Load calculation function of target Java VM**

Memory Pool Monitor ☒

**Control of distributed nodes**

Cut off an obstacle node dynamically ☐

Restart Command

Timeout  sec

**Properties - Monitor(special) tab -> Tuning properties- Load Balancer Linkage tab**  
**Select the Memory Pool Monitor check box.**

- Custom monitor resource

**Properties - Monitor(common) tab**  
**Select the Monitor Timing - Always radio button.**

**Properties - Monitor(special) tab**

**Select Script created with this product.**

**Select File -> Edit, then add the following highlighted text:**

```
#!/bin/sh
#*****
#*   genw.sh                               *
#*****

ulimit -s unlimited
${CLP_PATH}/ha/jra/bin/clpjra_bigip weight
exit 0
```

**Select the Monitor Type - Synchronous radio button.**

In the BIG-IP LTM setting, specify **Ratio(node)** in **LocalTraffic - Pools:PoolList - Relevant pool - Members - LoadBalancing - Load Balancing Method** of BIG-IP Configuration Utility.

- Configuring the load calculation function
  - Command execution interval: **Properties -> Monitor(common) tab -> Interval** seconds

Fig. 4.79: Load calculation function

#### 4.43.6 JVM statistics log

JVM monitor resources collect statistics information on the monitor target Java VM. The information is stored in CSV-format files, as JVM statistics logs. The file is created in the following location:

`<EXPRESSCLUSTER_install_path>/log/ha/jra/*.stat`

The following "monitor items" see the parameters on the [Monitor(special)] tab of [Properties] of the JVM monitor resources.

Statistical information is collected and output to its corresponding JVM statistical log when an item is selected and the threshold value is set for the item. If a monitor item is not selected, statistical information on the item will be neither collected nor output to its corresponding JVM statistical log.

The following table lists the monitor items and the corresponding JVM statistics logs.

Monitor items	Corresponding JVM statistics log
[Memory] tab - [Monitor Heap Memory Rate] [Memory] tab - [Monitor Non-Heap Memory Rate] [Memory] tab-[Monitor Heap Memory Usage] [Memory] tab -[Monitor Non-Heap Memory Usage]	jramemory.stat
[Thread] tab - [Monitor the number of Active Threads]	jrathread.stat
[GC] tab - [Monitor the time in Full GC] [GC] tab - [Monitor the count of Full GC execution]	jragc.stat
[WebLogic] tab - [Monitor the requests in Work Manager] [WebLogic] tab - [Monitor the requests in Thread Pool] When either of the above monitor items is checked, both of the logs, such as wlworkmanager.stat and wlthreadpool.stat, are output. No functions to output only one of the two logs are provided.	wlworkmanager.stat wlthreadpool.stat

#### 4.43.7 Java memory area usage check on monitor target Java VM (jramemory.stat)

The jramemory.stat log file records the size of the Java memory area used by the monitor target Java VM. Its file name will be either of the following, depending on the Rotation Type selected in the Log Output Setting dialog box.

- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [File Capacity] is selected: jramemory<integer\_starting\_with\_0>.stat
- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [Period] is selected: jramemory<YYYYMMDDhhmm>.stat

The data format is as follows.

No	Format	Description
1	yyyy/mm/dd hh:mm:ss.SSS	Date and time of log recording
2	Half-size alphanumeric characters and symbols	Name of the monitor target Java VM; this is specified in [Properties] - [Monitor(special)] tab - [Identifier] in JVM monitor resources.
3	Half-size alphanumeric characters and symbols	Name of the Java memory pool; for details, refer to "Java memory pool name".
4	Half-size alphanumeric characters and symbols	Type of Java memory pool Heap, Non-Heap

Continued on next page

Table 4.58 – continued from previous page

No	Format	Description
5	Half-size numeric characters	<p>Memory size that the Java VM requests from the OS at startup; this is expressed in bytes. (init)</p> <p>At the startup of the monitor target Java VM, the size can be specified using the following Java VM startup options.</p> <ul style="list-style-type: none"> <li>• HEAP:-Xms</li> <li>• NON_HEAP permanent area (Perm Gen): -XX:PermSize</li> <li>• NON_HEAP code cache area (Code Cache): -XX:InitialCodeCacheSize</li> </ul>
6	Half-size numeric characters	Memory size currently used by the Java VM; this is expressed in bytes. (used)
7	Half-size numeric characters	<p>Memory size guaranteed for use by the operation of the Java VM; this is expressed in bytes. (committed)</p> <p>This size varies depending on the memory use; it is always equal to the value of "used" or larger but equal to or smaller than the value of "max".</p>
8	Half-size numeric characters	<p>Maximum memory size that the Java VM can use; this is expressed in bytes. (max)</p> <p>The size can be specified using the following Java VM startup options.</p> <ul style="list-style-type: none"> <li>• HEAP:-Xmx</li> <li>• NON_HEAP permanent area (Perm Gen): -XX:MaxPermSize</li> <li>• NON_HEAP code cache area (Code Cache): -XX:ReservedCodeCacheSize</li> </ul> <p>Example)</p> <pre>java -XX:MaxPermSize=128m -XX:ReservedCodeCacheSize=128m javaAP</pre> <p>In this example, max of NON_HEAP becomes 128 m + 128 m = 256 m.</p> <p>(Note)</p> <p>When the same value is specified for -Xms and -Xmx, "init" may become larger than "max". This is because "max" of HEAP is determined by subtracting half the size of the Survivor Space from the area size determined by the specification of -Xmx.</p>
9	Half-size numeric characters	Peak size of the memory used after startup of the measurement target Java VM; when the name of the Java memory pool is HEAP or NON_HEAP, this size becomes equal to that of the memory currently used by the Java VM (used). This is expressed in bytes.

Continued on next page

Table 4.58 – continued from previous page

No	Format	Description
10	Half-size numeric characters	<p>Ignore when Oracle Java (usage monitoring) is selected for [JVM Type].</p> <p>When an item other than [Oracle Java (usage monitoring)] is selected for JVM Type, memory size equal to "max" (No. 8 field) * the threshold (%) when the Java memory pool type (No. 4 field) is HEAP; it is expressed in bytes. When the Java memory pool type is other than HEAP, it is 0.</p>

#### 4.43.8 Thread operation status check on monitor target Java VM (jthread.stat)

The jthread.stat log file records the thread operation status of the monitor target Java VM. Its file name will be either of the following depending on the Rotation Type selected in the Log Output Setting dialog box.

- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [File Capacity] is selected: jthread<integer\_starting\_with\_0>.stat
- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [Period] is selected: jthread<YYYYMMDDhhmm>.stat

The data format is as follows.

No	Format	Description
1	yyyy/mm/dd hh:mm:ss.SSS	Date and time of log recording
2	Half-size alphanumeric characters and symbols	Name of the monitor target Java VM; this is specified in [Properties] - [Monitor(special)] tab - [Identifier] in JVM monitor resources.
3	Half-size alphanumeric characters and symbols	Number of active threads in the monitor target Java VM
4	[Half-size numeric characters: half-size numeric characters:...]	Deadlocked thread ID in the monitor target Java VM; this contains the IDs of all the deadlocked threads, in order.
5	Half-size alphanumeric characters and symbols	<p>Detailed information on deadlocked threads in the monitor target Java VM; it contains information on all the deadlocked threads, in order, in the following format.</p> <p>ThreadName, ThreadID, ThreadStatus, UserTime, CpuTime, WaitedCount, WaitedTime, isInNative, isSuspended &lt;line feed&gt;  stacktrace&lt;line feed&gt;  :  stacktrace&lt;line feed&gt;  stacktrace=ClassName, FileName, LineNumber, MethodName, isNativeMethod</p>

#### 4.43.9 GC operation status check on monitor target Java VM (jragc.stat)

The jragc.stat log file records the GC operation status of the monitor target Java VM. Its file name will be either of the following, depending on the Rotation Type selected in the Log Output Setting dialog box.

- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type]-[File Capacity] is selected: jragc<integer\_starting\_with\_0>.stat
- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [Period] is selected: jragc<YYYYMMDDhhmm>.stat

JVM monitor resources output two types of GC information: Copy GC and Full GC.

With Oracle Java, JVM monitor resources count the increment in the count of execution of the following GC as Full GC.

- MarkSweepCompact
- MarkSweepCompact
- PS MarkSweep
- ConcurrentMarkSweep

The data format is as follows.

No	Format	Description
1	yyyy/mm/dd hh:mm:ss.SSS	Date and time of log recording
2	Half-size alphanumeric characters and symbols	Name of the monitor target Java VM; this is specified in [Properties] - [Monitor(special)] tab - [Identifier] in JVM monitor resources.

Continued on next page

Table 4.60 – continued from previous page

No	Format	Description
3	Half-size alphanumeric characters and symbols	<p>GC name of monitor target Java VM</p> <p><b>When the monitor target Java VM is Oracle Java</b> Copy MarkSweepCompact The GC name to be indicated is one of the following. MarkSweepCompact PS Scavenge PS MarkSweep ParNew ConcurrentMarkSweep</p> <p><b>When the monitor target Java VM is Oracle JRockit</b> The GC name to be indicated is one of the following. Garbage collection optimized for throughput Old Collector Garbage collection optimized for short pausetimes Old Collector Garbage collection optimized for deterministic pausetimes Old Collector Static Collector Static Old Collector Garbage collection optimized for throughput Young Collector</p>
4	Half-size numeric characters	Count of GC execution during the period from startup of the monitor target Java VM to measurement; the count includes the GC executed before the JVM monitor resource starts monitoring.
5	Half-size numeric characters	Total time in GC execution during the period from startup of the monitor target Java VM to measurement; this is expressed in milliseconds. This includes the time taken for the GC executed before the JVM monitor resource starts monitoring.

#### 4.43.10 Operation status check on Work Manager of WebLogic Server (wlworkmanager.stat)

The wlworkmanager.stat log file records the operation status of the Work Manager of the WebLogic Server. Its file name will be either of the following depending on the Rotation Type selected in the Log Output Setting dialog box.

- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [File Capacity] is selected: wlworkmanager<integer\_starting\_with\_0>.stat
- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [Period] is selected: wlworkmanager<YYYYMMDDhhmm>.stat

The data format is as follows.

No	Format	Description
1	yyyy/mm/dd hh:mm:ss.SSS	Date and time of log recording
2	Half-size alphanumeric characters and symbols	Name of the monitor target Java VM; this is specified in [Properties] - [Monitor(special)] tab - [Identifier] in JVM monitor resources.
3	Half-size alphanumeric characters and symbols	Application name
4	Half-size alphanumeric characters and symbols	Work Manager name
5	Half-size numeric characters	Request execution count
6	Half-size numeric characters	Number of wait requests

#### 4.43.11 Operation status check on Thread Pool of WebLogic Server (wlthreadpool.stat)

The wlthreadpool.stat log file records the operation status of the thread pool of the WebLogic Server. Its file name will be either of the following depending on the Rotation Type selected in the Log Output Setting dialog box.

- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [File Capacity] is selected: wlthreadpool<integer\_starting\_with\_0>.stat
- When Cluster Properties - [JVM monitor] tab - [Log Output Setting] - [Rotation Type] - [Period] is selected: wlthreadpool<YYYYMMDDhhmm>.stat

The data format is as follows.

No	Format	Description
1	yyyy/mm/dd hh:mm:ss.SSS	Date and time of log recording
2	Half-size alphanumeric characters and symbols	Name of monitor target Java VM; this is specified in [Properties] - [Monitor(special)] tab - [Identifier] in JVM monitor resources.
3	Half-size numeric characters	Total request execution count
4	Half-size numeric characters	Number of requests queued in the WebLogic Server
5	Half-size numeric characters	Request execution per unit time count (seconds)
6	Half-size numeric characters	Number of threads for executing the application
7	Half-size numeric characters	Number of threads in idle state
8	Half-size numeric characters	Number of executing threads
9	Half-size numeric characters	The number of threads in stand-by state

#### 4.43.12 Java memory pool name

This section describes the Java memory pool name output as memory\_name in messages to the JVM operation log file. It also describes the Java memory pool name output to the JVM statistics log file, jramemory.stat log file.

The character strings of the Java memory pool names are not determined by the JVM monitor resources. Character strings received from the monitor target Java VM are output as Java memory pool names.

Their specifications are not open for Java VM, and accordingly, are subject to change without notice with any version upgrade of Java VM.

Therefore, we do not recommend monitoring Java memory pool names contained in messages.

The following monitor items see the parameters on the [Memory] tab of the [Monitor(special)] tab in [Properties] of the JVM monitor resources.

The following Java memory pool names have been confirmed on actual machines running Oracle Java and JRockit.

When **Oracle Java** is selected for **JVM Type**, and "-XX:+UseSerialGC" is specified as a startup option for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat log file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Rate] - [Total Usage]	HEAP
[Monitor Heap Memory Rate] - [Eden Space]	Eden Space
[Monitor Heap Memory Rate] - [Survivor Space]	Survivor Space
[Monitor Heap Memory Rate] - [Tenured Gen]	Tenured Gen
[Monitor Non-Heap Memory Rate] - [Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Rate] - [Code Cache]	Code Cache
[Monitor Non-Heap Memory Rate] - [Perm Gen]	Perm Gen
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-ro]]	Perm Gen [shared-ro]
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-rw]]	Perm Gen [shared-rw]

When **Oracle Java** is selected for **JVM Type**, and "-XX:+UseParallelGC" and "-XX:+UseParallelOldGC" are specified as the startup options for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat log file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Rate] - [Total Usage]	HEAP
[Monitor Heap Memory Rate] - [Eden Space]	PS Eden Space
[Monitor Heap Memory Rate] - [Survivor Space]	PS Survivor Space
[Monitor Heap Memory Rate] - [Tenured Gen]	PS Old Gen
[Monitor Non-Heap Memory Rate] - [Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Rate] - [Code Cache]	Code Cache
[Monitor Non-Heap Memory Rate] - [Perm Gen]	PS Perm Gen
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-ro]]	Perm Gen [shared-ro]
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-rw]]	Perm Gen [shared-rw]

When **Oracle Java** is selected for **JVM Type**, and "-XX:+UseConcMarkSweepGC" is specified as a startup option for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat log file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Rate] - [Total Usage]	HEAP
[Monitor Heap Memory Rate] - [Eden Space]	Par Eden Space
[Monitor Heap Memory Rate] - [Survivor Space]	Par Survivor Space
[Monitor Heap Memory Rate] - [Tenured Gen]	CMS Old Gen
[Monitor Non-Heap Memory Rate] - [Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Rate] - [Code Cache]	Code Cache
[Monitor Non-Heap Memory Rate] - [Perm Gen]	CMS Perm Gen
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-ro]]	Perm Gen [shared-ro]

Continued on next page

Table 4.65 – continued from previous page

Monitor item	Character string output as memory_name
[Monitor Non-Heap Memory Rate] - [Perm Gen[shared-rw]]	Perm Gen [shared-rw]

When [Oracle Java(usage monitoring)] is selected for [JVM Type] and "-XX:+UseSerialGC" is specified as a startup option for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Usage]-[Total Usage]	HEAP
[Monitor Heap Memory Usage]-[Eden Space]	Eden Space
[Monitor Heap Memory Usage]-[Survivor Space]	Survivor Space
[Monitor Heap Memory Usage]-[Tenured Gen]	Tenured Gen
[Monitor Non-Heap Memory Usage]-[Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Usage]-[Code Cache]	Code Cache (For Java 9 or later, no output)
[Monitor Non-Heap Memory Usage]-[Metaspace]	Metaspace
[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods
[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space

When [Oracle Java(usage monitoring)] is selected for [JVM Type] and "-XX:+UseParallelGC" and "-XX:+UseParallelOldGC" are specified as startup options for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Usage]-[Total Usage]	HEAP
[Monitor Heap Memory Usage]-[Eden Space]	PS Eden Space
[Monitor Heap Memory Usage]-[Survivor Space]	PS Survivor Space
[Monitor Heap Memory Usage]- [Tenured Gen]	PS Old Gen
[Monitor Non-Heap Memory Usage]-[Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Usage]-[Code Cache]	Code Cache (For Java 9 or later, no output)
[Monitor Non-Heap Memory Usage]-[Metaspace]	Metaspace
[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods
[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space

When [Oracle Java(usage monitoring)] is selected for [JVM Type] and "-XX:+UseConcMarkSweepGC" is specified as a startup option for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Usage]-[Total Usage]	HEAP
[Monitor Heap Memory Usage]-[Eden Space]	Par Eden Space
[Monitor Heap Memory Usage]-[Survivor Space]	Par Survivor Space
[Monitor Heap Memory Usage]-[Tenured Gen]	CMS Old Gen
[Monitor Non-Heap Memory Usage]-[Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Usage]-[Code Cache]	Code Cache (For Java 9 or later, no output)
[Monitor Non-Heap Memory Usage]-[Metaspace]	Metaspace
[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods
[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space

When [Oracle Java(usage monitoring)] is selected for [JVM Type] and "-XX:+UseParNewGC" is specified as a startup option for the monitor target Java VM, the No. 3 Java memory pool name in the jramemory.stat file will be as follows. For Java 9 or later, if -XX:+UseParNewGC is specified, the monitor target Java VM does not start.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Usage]-[Total Usage]	HEAP
[Monitor Heap Memory Usage]-[Eden Space]	Par Eden Space
[Monitor Heap Memory Usage]-[Survivor Space]	Par Survivor Space
[Monitor Heap Memory Usage]-[Tenured Gen]	Tenured Gen
[Monitor Non-Heap Memory Usage]-[Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Usage]-[Code Cache]	Code Cache
[Monitor Non-Heap Memory Usage]-[Metaspace]	Metaspace
[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods
[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space

When [Oracle Java(usage monitoring)] is selected for [JVM Type] and "-XX:+UseG1GC" is specified as a startup option for the monitor target Java VM the No. 3 Java memory pool name in the jramemory.stat file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Usage]-[Total Usage]	HEAP
[Monitor Heap Memory Usage]-[Eden Space]	G1 Eden Space
[Monitor Heap Memory Usage]-[Survivor Space]	G1 Survivor Space
[Monitor Heap Memory Usage]-[Tenured Gen (Old Gen)]	G1 Old Gen
[Monitor Non-Heap Memory Usage]-[Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Usage]-[Code Cache]	Code Cache (For Java 9 or later, no output)
[Monitor Non-Heap Memory Usage]-[Metaspace]	Metaspace

Table 4.70 – continued from previous page

Monitor item	Character string output as memory_name
[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods
[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods
[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space

When the monitor target Java VM is Oracle JRockit (when [JRockit] is selected for [JVM Type]), the No. 3 Java memory pool name in the jramemory.stat log file will be as follows.

Monitor item	Character string output as memory_name
[Monitor Heap Memory Rate] - [Total Usage]	HEAP memory
[Monitor Heap Memory Rate] - [Nursery Space]	Nursery
[Monitor Heap Memory Rate] - [Old Space]	Old Space
[Monitor Non-Heap Memory Rate] - [Total Usage]	NON_HEAP
[Monitor Non-Heap Memory Rate] - [Class Memory]	Class Memory

**Java memory pool names appearing in the jramemory.stat log file, a JVM statistics log file, correspond to the Java VM memory space as follows.**

- For Oracle Java 7

Fig. 4.80: Java VM memory space (Oracle Java 7)

(6)	[Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods]	CodeHeap non-nmethods (Only for Java 9 or later, it is output.)
(6)	[Monitor Non-Heap Memory Usage]-[CodeHeap profiled]	CodeHeap profiled nmethods (Only for Java 9 or later, it is output.)
(6)	[Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled]	CodeHeap non-profiled nmethods (Only for Java 9 or later, it is output.)
(7)	[Monitor Non-Heap Memory Usage] - [Metaspace]	Metaspace
(8)	[Monitor Non-Heap Memory Usage]-[Compressed Class Space]	Compressed Class Space
(6)+(7)+(8)	[Monitor Non-Heap Memory Usage] - [Total Usage]	NON_HEAP

- For Oracle JRockit

Fig. 4.82: Java VM memory space (Oracle JRockit)

No. in diagram	Monitor item	Java memory pool name in jramemory.stat log file
(1)	[Monitor Heap Memory Rate] - [Total Usage]	HEAP memory
(2)	[Monitor Heap Memory Rate] - [Nursery Space]	Nursery
(3) (Note)	[Monitor Heap Memory Rate] - [Old Space]	Old Space
-	[Monitor Non-Heap Memory Rate] - [Total Usage]	NON_HEAP
-	[Monitor Non-Heap Memory Rate] - [Class Memory]	Class Memory

**Note:** "Old Space", a Java memory pool name in the jramemory.stat log file, does not indicate the value corresponding to the old space of the Heap but rather the value corresponding to the entire "Heap memory". Independent measurement of only (3) is not possible.

#### 4.43.13 Executing a command corresponding to cause of each detected error

EXPRESSCLUSTER does not provide a means for executing specific commands based on the causes of detected monitor resource errors.

JVM monitor resources can execute specific commands according to error causes. If an error is detected, JVM monitor resources will execute an appropriate command.

The following setting items specify the commands that will be executed according to the error cause.

Error cause	Setting item
<ul style="list-style-type: none"> <li>- Failure in connection to the monitor target Java VM</li> <li>- Failure in resource measurement</li> </ul>	[Monitor(special)] tab - [Command]

Continued on next page

Table 4.75 – continued from previous page

Error cause	Setting item
<ul style="list-style-type: none"> <li>- Heap memory rate</li> <li>- Non-heap memory rate</li> <li>- Heap memory usage</li> <li>- Non-heap memory usage</li> </ul>	[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Command]
<ul style="list-style-type: none"> <li>- Number of active threads</li> </ul>	[Monitor(special)] tab - [Tuning] properties - [Thread] tab - [Command]
<ul style="list-style-type: none"> <li>- Time in Full GC</li> <li>- Count of Full GC execution</li> </ul>	[Monitor(special)] tab - [Tuning] properties - [GC] tab - [Command]
<ul style="list-style-type: none"> <li>- Requests in Work Manager of WebLogic</li> <li>- Requests in Thread Pool of WebLogic</li> </ul>	[Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Command]

[Command] passes the details of an error cause as the arguments of a command with the arguments attached to the end of [Command]. A Command that is specialized for dealing with specific error causes can be defined by designing and specifying a script etc. for [Command]. The following character strings are passed as the arguments.

When multiple character strings are stated as possible arguments, one will be passed according to the GC type of the monitor target Java VM. For details about their differences, see "Java memory pool name".

The statements "(For Oracle Java)" and "(For Oracle JRockit)" suggest that different character strings are used according to the JVM type. When there is no such statement, the same character strings are used equally for all JVM types.

Details of error causes	Character string passed as argument
<ul style="list-style-type: none"> <li>- Failure in connection to the monitor target Java VM</li> <li>- Failure in resource measurement</li> </ul>	No character string defined
[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Monitor Memory Heap Rate] - [Total Usage] (For Oracle Java)	HEAP

Details of error causes	Character string passed as argument
[Memory] tab - [Monitor Non-Heap Memory Usage] - [Total Usage] (for Oracle Java(usage monitoring))	NON_HEAP
[Memory] tab - [Monitor Non-Heap Memory Usage] - [Code Cache] (for Oracle Java(usage monitoring))	CodeCache
[Memory] tab - [Monitor Non-Heap Memory Usage] - [Metaspace] (for Oracle Java(usage monitoring))	Metaspace
[Memory] tab - [Monitor Non-Heap Memory Usage]-[CodeHeap non-nmethods] (when Oracle Java (usage monitoring) is selected)	non-nmethods
[Memory] tab - [Monitor Non-Heap Memory Usage]-[CodeHeap profiled] (when Oracle Java (usage monitoring) is selected)	profilednmethods
[Memory] tab - [Monitor Non-Heap Memory Usage]-[CodeHeap non-profiled] (when Oracle Java (usage monitoring) is selected)	non-profilednmethods
[Memory] tab - [Monitor Non-Heap Memory Usage]-[Compressed Class Space] (when Oracle Java (usage monitoring) is selected)	CompressedClassSpace
[Memory] tab - [Monitor Memory Heap Rate] - [Total Usage] (For Oracle JRockit)	HEAP Heap
[Memory] tab - [Monitor Memory Heap Rate] - [Nursery Space] (For Oracle JRockit)	Nursery
[Memory] tab - [Monitor Memory Heap Rate] - [Old Space] (For Oracle JRockit)	OldSpace
[Memory] tab - [Monitor Memory Non-Heap Rate] - [Total Usage] (For Oracle JRockit)	NON_HEAP
[Memory] tab - [Monitor Memory Non-Heap Rate] - [Class Memory] (For Oracle JRockit)	ClassMemory
[Thread] tab - [Monitor the number of Active Threads]	Count
[GC] tab - [Monitor the time in Full GC]	Time
[GC] tab - [Monitor the count of Full GC execution]	Count
[WebLogic] tab - [Monitor the requests in Work Manager] - [Waiting Requests, The number]	WorkManager_PendingRequests
[WebLogic] tab - [Monitor the requests in Thread Pool] - [Waiting Requests, The number]	ThreadPool_PendingUserRequestCount
[WebLogic] tab - [Monitor the requests in Thread Pool] - [Executing Requests, The number]	ThreadPool_Throughput

The following are examples of execution.

Example 1)

Setting item	Setting information
[Monitor(special)] tab - [Tuning] properties - [GC] tab - [Command]	/usr/local/bin/downcmd
[Monitor(special)] tab - [Tuning] properties - [GC] tab - [Monitor the count of Full GC execution]	1
[Cluster] properties - [JVM monitor] tab - [Resource Measurement Setting] - [Common] tab - [Error Threshold]	3

If Full GC is executed as many times, in succession, as specified by the Error Threshold (three times), the JVM monitor resources will detect a monitor error and execute a command corresponding to "/usr/local/bin/downcmd Cont".

Example 2)

Setting item	Setting information
[Monitor(special)] tab - [Tuning] properties - [GC] tab - [Command]	"usr/local/bin/downcmd" GC
[Monitor(special)] tab - [Tuning] properties - [GC] tab - [Monitor the time in Full GC]	65536
[Cluster] properties - [JVM monitor] tab - [Resource Measurement Setting] - [Common] tab - [Error Threshold]	3

If the time in Full GC exceeds 65535 milliseconds as many times, in succession, as specified by the Error Threshold (three times), the JVM monitor resources will detect a monitor error and execute a command corresponding to "/usr/local/bin/downcmd GC Time".

Example 3)

Setting item	Setting information
[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Command]	"usr/local/bin/downcmd" memory
[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Monitor Heap Memory Rate]	On
[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Eden Space]	80
[Monitor(special)] tab - [Tuning] properties - [Memory] tab - [Survivor Space]	80
[Cluster] properties - [JVM monitor] tab - [Resource Measurement Setting] - [Common] tab - [Error Threshold]	3

If the usage rate of the Java Eden Space and that of the Java Survivor Space exceed 80% as many times, in succession, as specified by the Error Threshold (three times), the JVM monitor resources will detect a monitor error and execute a command corresponding to "/usr/local/bin/downcmd memory EdenSpace SurvivorSpace".

Timeout (seconds) for waiting for the completion of execution of the command specified by [Command] is set by specifying [Command Timeout] in the [JVM monitor] tab of the Cluster Properties window. The same value is applied to the timeout of [Command] of each of the above-mentioned tabs; the timeout cannot be specified for each [Command] separately.

If a timeout occurs, the system will not perform processing for forced termination of the [Command] process; the operator must perform post-processing (e.g. forced termination) of the [Command] process. When a timeout occurs, the following message is output to the JVM operation log:

action thread execution did not finish. action is alive = <command>.

Note the following.

1. No [Command] is executed when restoration of the Java VM to normal operation (error -> normal operation) is detected.

2. [Command] is executed upon the detection of an error in the Java VM (when threshold exceeding occurs as many times, in succession, as specified by the error threshold). It is not executed at each threshold exceeding.
3. Note that specifying [Command] on multiple tabs allows multiple commands to be executed if multiple errors occur simultaneously, causing a large system load.
4. [Command] may be executed twice simultaneously when the following two items are monitored: [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Work Manager] - [Waiting Requests, The Number]; [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Work Manager] - [Waiting Requests, Average].

This is because errors may be detected simultaneously for the following two items: [Cluster] properties - [JVM monitor] tab - [Resource Measurement Setting] - [WebLogic] tab - [Interval, The number of request]; [Cluster] properties - [JVM monitor] tab - [Resource Measurement Setting] - [WebLogic] tab - [Interval, The average number of the request]. To prevent this from occurring, specify only one of the two items as a monitor target. This applies to the following combinations of monitor items.

- [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Thread Pool] - [Waiting Requests, The Number] and [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Thread Pool] - [Waiting Requests, Average]
- [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Thread Pool] - [Executing Requests, The Number] and [Monitor(special)] tab - [Tuning] properties - [WebLogic] tab - [Monitor the requests in Thread Pool] - [Executing Requests, Average]

#### 4.43.14 Monitoring WebLogic Server

For how to start the operation of the configured target WebLogic Server as an application server, see the manual for WebLogic Server.

This section describes only the settings required for monitoring by the JVM monitor resource.

1. Start WebLogic Server Administration Console.  
For how to start WebLogic Server Administration Console, refer to "Overview of Administration Console" in the WebLogic Server manual.  
Select **Domain Configuration-Domain-Configuration-General**. Make sure that **Enable Management Port** is **unchecked**.
2. Select **Domain Configuration-Server**, and then select the name of the server to be monitored. Set the selected server name as the identifier on the **Monitor(special)** tab from **Properties** that can be selected in the the config mode of Cluster WebUI. See "*Understanding JVM monitor resources*".
3. Regarding the target server, select **Configuration-General**, and then check the port number though which a management connection is established with **Listen Port**.
4. Stop WebLogic Server. For how to stop WebLogic Server, refer to "Starting and stopping WebLogic Server" in the WebLogic Server manual.
5. Start the management server start script of WebLogic Server (startWebLogic.sh).
6. Write the following instructions in the script.

- When the target is the WebLogic Server managing server:

```
JAVA_OPTIONS="$ {JAVA_OPTIONS}
-Dcom.sun.management.jmxremote.port=n
-Dcom.sun.management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.authenticate=false
-Djavax.management.builder.initial=weblogic.management.jmx.mbeanserver.
↳ WLSMBeanServerBuilder"
```

\*Write each line of coding on one line.

- When the target is a WebLogic Server managed server:

```
if [ "${SERVER_NAME}" = "SERVER_NAME" ]; then
JAVA_OPTIONS="${JAVA_OPTIONS}"
-Dcom.sun.management.jmxremote.port=n
-Dcom.sun.management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.authenticate=false
-Djavax.management.builder.initial=weblogic.management.jmx.mbeanserver.
↪WLSMBeanServerBuilder"
```

\*Write all the if statement lines (lines 2 to 5) on one line.

**Note:** For **n**, specify the number of the port used for monitoring. The specified port number **must be different from that of the listen port for the target Java VM**. If there are other target WebLogic Server entities on the same machine, specify a port number different from those for the listening port and application ports of the other entities.

**Note:** For **SERVER\_NAME**, specify the name of the target server confirmed by **Select Target Server**. If more than one server is targeted, change the server name on the settings (line 1 to 6) for each server.

**Note:** Place the above addition prior to the following coding:

```
${JAVA_HOME}/bin/java ${JAVA_VM} ${MEM_ARGS} ${JAVA_OPTIONS}
-Dweblogic.Name=${SERVER_NAME} -Djava.security.policy=${WL_HOME}/server/lib/weblogic.policy
${PROXY_SETTINGS} ${SERVER_CLASS}
```

\* Write the above coding on one line.

\* The above java arguments differ depending on the WebLogic version. There is no problem by specifying JAVA\_OPTIONS before using java.

**Note:** For monitoring **Perm Gen[shared-ro]** or **Perm Gen[shared-rw]** on the **Memory** tab, add the following line:

**-client -Xshare:on -XX:+UseSerialGC**

7. If monitoring requests of work manager and thread pool, make the following settings.

Start WLST (wlst.sh) of the target WebLogic Server. On the console window displayed, execute the following commands:

```
>connect ('USERNAME', 'PASSWORD', 't3://SERVER_ADDRESS:SERVER_PORT')
> edit ()
> startEdit ()
> cd ('JMX/DOMAIN_NAME')
> set ('PlatformMBeanServerUsed', 'true')
> activate ()
> exit ()
```

Replace the **USERNAME**, **PASSWORD**, **SERVER\_ADDRESS**, **SERVER\_PORT**, and **DOMAIN\_NAME** above with those for the domain environment.

8. Restart the target WebLogic Server.

#### 4.43.15 Monitoring WebOTX

This guide describes how to configure a target WebOTX to enable monitoring by the JVM monitor resource.

Start the WebOTX Administration Console. For how to start the WebOTX Administration Console, refer to "Starting and stopping administration tool" in the *WebOTX Operation (Web Administration Tool)*.

The settings differ depending on whether a Java process of the JMX agent running on WebOTX or the Java process of a process group is to be monitored. Configure the settings according to the target of monitoring.

#### 4.43.16 Monitoring a Java process of the WebOTX domain agent

There is no need to specify any settings.

#### 4.43.17 Monitoring a Java process of a WebOTX process group

1. Connect to the domain by using the administration tool.
2. In the tree view, select **<domain\_name>-TP System-Application Group-<application\_group\_name>-Process Group-<process\_group\_name>**.
3. For the **Other Arguments** attributes on the **JVM Options** tab on the right, specify the following Java options on one line. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified for the settings is specified with Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special) tab -> Connection Port**).

```
-Dcom.sun.management.jmxremote.port=n  
-Dcom.sun.management.jmxremote.ssl=false  
-Dcom.sun.management.jmxremote.authenticate=false  
-Djavax.management.builder.initial=com.nec.webotx.jmx.mbeanserver.  
↪ JmxMBeanServerBuilder
```

\* In the case of WebOTX V9.2 or later, it is unnecessary to specify `-Djavax.management.builder.initial`.

4. Then, click **Update**. After the configuration is completed, restart the process group.

These settings can be made by using **Java System Properties**, accessible from the **Java System Properties** tab of the WebOTX administration tool. When making these settings by using the tool, do not designate `-D` and set the strings prior to `=` in name and set the strings subsequent to `=` in value.

---

**Note:** If restart upon a process failure is configured as a function of the WebOTX process group, and when the process group is restarted as the recovery processing by EXPRESSCLUSTER, the WebOTX process group may fail to function correctly. For this reason, when monitoring the WebOTX process group, make the following settings for the JVM monitor resource by using the Cluster WebUI.

Tab name for setting	Item name	Setting value
Monitor(common)	Monitor Timing	Always
Recovery Action	Recovery Action	Execute only the final action
Recovery Action	Final Action	No operation

Linking with the load balancer is not supported for WebOTX process group monitoring.

#### 4.43.18 Receiving WebOTX notifications

By registering a specific listener class, notification is issued when WebOTX detects a failure. The JVM monitor resource receives the notification and outputs the following message to the JVM operation log.

%1\$s:Notification received. %2\$s.

%1\$s and %2\$s each indicates the following:

%1\$s: Monitored Java VM

%2\$s: Message in the notification (ObjectName=\*\*,type=\*\*,message=\*\*)

At present, the following is the detailed information on MBean on the monitorable resource.

ObjectName	[domainname]:j2eeType=J2EEDomain,name=[domainname],category=runtime
notification type	nec.webotx.monitor.alivecheck.not-alive
Message	failed

#### 4.43.19 Monitoring JBoss

The settings are different for monitoring standalone mode and for domain mode. Configure the settings according to the target of monitoring.

This section describes how to configure a target JBoss to be monitored by the JVM monitor resource.

Standalone mode

1. Stop JBoss, and then open (*JBoss\_installation\_path*)/bin/standalone.conf by using editor software.
2. In the configuration file, specify the following settings. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified for the settings is specified with Cluster WebUI (JVM Monitor Resource Name -> Properties -> Monitor(special) tab -> Connection Port).

Add the following before "if [ "x\$JBASS\_MODULES\_SYSTEM\_PKGS" = "x" ]; then".

```
JBASS_MODULES_SYSTEM_PKGS="org.jboss.logmanager"
```

Add the following after "if [ "x\$JAVA\_OPTS" = "x" ]; then ... fi".

```
JAVA_OPTS="$JAVA_OPTS -Xbootclasspath/p:$JBASS_HOME/modules/org/jboss/logmanager/
↪main/jboss-logmanager-1.3.2.Final-redhat-1.jar"
JAVA_OPTS="$JAVA_OPTS -Djava.util.logging.manager=org.jboss.logmanager.LogManager"
JAVA_OPTS="$JAVA_OPTS -Dcom.sun.management.jmxremote.port=n -Dcom.sun.management.
↪jmxremote.ssl=false -Dcom.sun.management.jmxremote.authenticate=false"
```

\* The storage directory and file name of jboss-logmanager-\*.jar differ depending on the JBoss version. Therefore, specify the path according to the installation environment.

3. Save the settings, and then start JBoss.
4. With Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)tab -> Identifier**), specify a unique string that is different from those for the other monitor targets (e.g. JBoss).

Domain mode

With Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)** tab -> **Identifier**), specify a unique string that is different from those for the other monitor targets (e.g. JBoss).  
With Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)** tab -> **Process Name**), specify all the Java VM startup options so that JBoss can be uniquely identified.

### 4.43.20 Monitoring Tomcat

This section describes how to configure a target Tomcat to be monitored by the JVM monitor resource.

1. If Tomcat is installed from an rpm package, stop Tomcat and open /etc/sysconfig/tomcat6 or /etc/sysconfig/tomcat. If Tomcat is not installed from an rpm package, stop Tomcat and create (*Tomcat installation path*)/bin/setenv.sh.
2. In the configuration file, for the Java options, specify the following settings on one line. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified for the settings is specified with Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)** tab -> **Connection Port**).

```
CATALINA_OPTS="$ ${CATALINA_OPTS}
-Dcom.sun.management.jmxremote.port=n
-Dcom.sun.management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.authenticate=false"
```

3. Save the settings, and then start Tomcat.
4. With Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)** tab -> **Identifier**), specify a unique string that is different from those for the other monitor targets (e.g., tomcat).

### 4.43.21 Monitoring SVF

This section describes how to configure a target SVF to be monitored by the JVM monitor resource.

If the monitor target is Tomcat:

Change the environment variables of the SVF user in the OS as follows. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified here is also specified with the Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special)** tab -> **Connection Port**).

```
JAVA_OPTS="-Xms512m -Xmx512m -Dcom.sun.management.jmxremote.port=n -Dcom.sun.
↪management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.authenticate=false"
export JAVA_OPTS
```

If the monitor target is other than Tomcat:

1. Select a monitor target from the following, and then use an editor to open the corresponding script.

Monitor target	Script to be edited
Simple Httpd Service (for 8.x)	<SVF installation path>/bin/SimpleHttpd
Simple Httpd Service (for 9.x)	<SVF installation path>/bin/UCXServer
RDE Service	<SVF installation path>/rdjava/rdserver/rd_server_startup.sh
	<SVF installation path>/rdjava/rdserver/svf_server_startup.sh
RD Spool Balancer	<SVF installation path>/rdjava/rdbalancer/rd_balancer_startup.sh
SVF Print Spooler Service	<SVF installation path>/bin/spooler

2. In the configuration file, for the Java options, specify the following settings on one line. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified here is also specified with the Cluster WebUI (**JVM Monitor Resource Name -> Properties -> Monitor(special) tab -> Connection Port**).

```
JAVA_OPTIONS="${JAVA_OPTIONS}  
-Dcom.sun.management.jmxremote.port=n  
-Dcom.sun.management.jmxremote.ssl=false  
-Dcom.sun.management.jmxremote.authenticate=false
```

3. If the monitor target is RDE Service, add \${JAVA\_OPTIONS} into the following startup path and rd\_balancer\_startup.sh

```
java -Xmx256m -Xms256m -Djava.awt.headless=true ${JAVA_OPTIONS}  
-classpath $CLASSPATH jp.co.fit.vfreport.RdSpoolPlayerServer &
```

#### 4.43.22 Monitoring a Java application that you created

This section describes the procedure to configure Java application which is monitored by JVM monitor resource. Specify the following Java option in one row to the option for Java application startup while Java application (the monitor target) is stopped. For **n**, specify the port number. If there is more than one Java VM to be monitored on the same machine, specify a unique port number. The port number specified here is also specified with the Cluster WebUI (**Monitor Resource Properties - Monitor(special) tab - Connection Port**).

```
-Dcom.sun.management.jmxremote.port=n  
-Dcom.sun.management.jmxremote.ssl=false  
-Dcom.sun.management.jmxremote.authenticate=false
```

Some Java applications require the following to be additionally specified.

```
- Djavax.management.builder.initial=<Class name of MBeanServerBuilder>
```

### 4.43.23 Monitor (special) tab

Monitor Resource Properties | jraw1

Info Monitor(common) **Monitor(special)** Recovery Action

Target: WebLogic Server

JVM Type: Oracle Java

Identifier\*: Server-0

Connection Port\*: 10002

Process Name:

User:

Password: Change

Command:

Tuning

OK Cancel Apply

#### Target

Select the target to be monitored from the list. When monitoring WebSAM SVF for PDF, WebSAM Report Director Enterprise, or WebSAM Universal Connect/X, select **WebSAM SVF**. When monitoring a Java application that you created, select **Java Application**.

Select [JBoss] when monitoring standalone mode of JBoss Enterprise Application Platform. Select "JBoss Domain Mode" when monitoring the domain mode of JBoss Enterprise Application Platform.

Default: None

#### JVM Type

Select the Java VM on which the target application to be monitored is running.

For Java 8 (or later) and OpenJDK 8 (or later) or later, select **Oracle Java(usage monitoring)**. For Java 8, the following specification changes have been made.

- It has become impossible to acquire the maximum value of each memory in a non-heap area.
- Perm Gen has been changed to Metaspace.
- Compressed Class Space was added.

For Java 8, therefore, the monitor items on the **Memory** tab have been changed as below.

- Monitoring for the use rate has been changed to monitoring for the amount used.
- **Perm Gen**, **Perm Gen[shared-ro]**, and **Perm Gen[shared-rw]** cannot be monitored. Clear the check box.
- **Metaspace** and **Compressed Class Space** can be monitored.

For Java 9, the following specification changes have been made.

- **Code Cache** has been divided.

For Java9, therefore, the monitor items on the **Memory** tab have been changed as below.

- **Code Cache** cannot be monitored. Clear the check box.
- **CodeHeap non-nmethods**, **CodeHeap profiled**, and **CodeHeap non-profiled** can be monitored.

For each monitor target, the following are selectable.

- When the target is **WebLogic Server**  
**Oracle Java**, **Oracle Java(usage monitoring)**, and **Oracle JRockit** are selectable
- When the target is **Tomcat**  
**Oracle Java**, **Oracle Java(usage monitoring)**, and **OpenJDK** are selectable.
- When the target is other than **WebLogic Server** and **Tomcat**  
**Oracle Java** and **Oracle Java(usage monitoring)** are selectable.

Default: None

#### Identifier (within 255 bytes)

The identifier is set to differentiate the relevant JVM monitor resource from another JVM monitor resource when the information on the application to be monitored is output to the JVM operation log of the relevant JVM monitor resource. For this purpose, set a unique character string between JVM monitor resources. You must specify the identifier.

- When the target is **WebLogic Server**  
Set the name of the server instance to be monitored, according to "*Monitoring WebLogic Server*", item 2.
- When the target is **WebOTX Process Group**  
Specify the name of the process group.
- When the target is **WebOTX Domain Agent**  
Specify the name of the domain.
- When the target is **JBoss or JBoss Domain Mode**  
Specify this according to "*Monitoring JBoss*".
- When the target is **Tomcat**  
Specify this according to "Monitoring Tomcat".
- When the target is **WebOTX ESB**  
Same as for **WebOTX Process Group**.
- When the target is **WebSAM SVF**  
Specify this according to "*Monitoring SVF*".
- When the target is **Java Application**  
Specify a uniquely identifiable string for the monitored Java VM process.

Default: None

#### Connection Port (1024 to 65535)

Set the port number used by the JVM monitor resource when it establishes a JMX connection to the target Java VM. The JVM monitor resource obtains information by establishing a JMX connection to the target Java VM. Therefore, to register the JVM monitor resource, it is necessary to specify the setting by which the JMX connection port is opened for the target Java VM. You must specify the connection port. This is common to all the servers in the cluster. A value between 42424 and 61000 is not recommended.

- When the target is **WebLogic Server**  
Set the connection port number according to "*Monitoring WebLogic Server*", item 6.
- When the target is **WebOTX Process Group**

Specify this according to "*Monitoring a Java process of a WebOTX process group*".

- When the target is **WebOTX Domain Agent**  
Specify "domain.admin.port" of "(WebOTX\_installation\_path)/<domain\_name>.properties".
- When the target is **JBoss**  
Specify as described in "*Monitoring JBoss*".
- When the target is **JBoss Domain Mode**  
The connection port number need not be specified.
- When the target is **Tomcat**  
Specify as described in "Monitoring Tomcat".
- When the target is **WebOTX ESB**  
Same as for **WebOTX Process Group**.
- When the target is **WebSAM SVF**  
Specify this according to "*Monitoring SVF*".
- When the target is **Java Application**  
Specify a uniquely identifiable string for the monitored Java VM process.

Default: None

#### Process Name (within 1024 bytes)

Set a **Process Name to identify** the target JVM monitor resource when JVM monitor resource is connecting the target Java VM via JMX. Therefore, be sure to specify a character string that is unique among JVM monitor resources.

- When the target is other than **JBoss Domain Mode**  
This does not need to be configured because the monitor target Java VM can be identified by **Connction Port Number**. The internal version 3.3.5-1 or earlier required the process name to be specified since this parameter was used for the identification when the data of virtual memory usage amount was obtained or when the data of the monitor target was output to the JVM operation log. However, in and after the internal version 4.0.0-1, **Monitor Virtual Memory Usage** was deleted. Therefore, it cannot be specified.
- When the target is **JBoss domain mode**  
Specify this according to "*Monitoring JBoss*".

Default: None

#### User (within 255 bytes)

Specify the name of the administrator who will be making a connection with the target Java VM.

- When **WebOTX Domain Agent** is selected as the target  
Specify the "domain.admin.user" value of "/opt/WebOTX/<domain\_name>.properties".
- When the target is other than **WebOTX Domain Agent**  
This cannot be specified.

Default: None

#### Password (within 255 bytes)

Specify the password for the administrator who will be making a connection with the target Java VM.

- When **WebOTX Domain Agent** is selected as the target  
Specify the "domain.admin.passwd" value of "/opt/WebOTX/<domain\_name>.properties".

- When the target is other than **WebOTX Domain Agent**  
This cannot be specified.

Default: None

#### Command (within 255 bytes)

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)  
"/usr/local/bin/command" arg1 arg2

Specify the commands that will be executed if connection to the monitor target Java VM cannot be established or if an error is detected in the process for acquiring the amount of resource usage on the Java VM.

See *"Executing a command corresponding to cause of each detected error"*.

Default: None

When you click **Tuning**, the following information is displayed in the pop-up dialog box. Make detailed settings according to the descriptions below.

### 4.43.24 Memory tab (when Oracle Java or OpenJDK is selected for JVM Type)

#### Monitor Heap Memory Rate

**JVM Monitor Resource Tuning Properties**

Memory Thread GC WebLogic Load Balancer Linkage

<input checked="" type="checkbox"/> <b>Monitor Heap Memory Rate</b>	<input checked="" type="checkbox"/> <b>Monitor Non-Heap Memory Rate</b>
<input checked="" type="checkbox"/> <b>Total Usage</b> 80 %	<input checked="" type="checkbox"/> <b>Total Usage</b> 80 %
<input type="checkbox"/> <b>Eden Space</b> 100 %	<input type="checkbox"/> <b>Code Cache</b> 100 %
<input type="checkbox"/> <b>Survivor Space</b> 100 %	<input checked="" type="checkbox"/> <b>Perm Gen</b> 80 %
<input checked="" type="checkbox"/> <b>Tenured Gen</b> 80 %	<input checked="" type="checkbox"/> <b>Perm Gen[shared-ro]</b> 80 %
<b>Command</b> <input type="text"/>	<input checked="" type="checkbox"/> <b>Perm Gen[shared-rw]</b> 80 %
<b>Initialize</b>	<b>Command</b> <input type="text"/>
<input type="button" value="OK"/> <input type="button" value="Cancel"/> <input type="button" value="Apply"/>	

Enables the monitoring of the usage rates of the Java heap areas used by the target Java VM.

- When the check box is selected (default):  
Monitoring enabled
- When the check box is not selected:  
Monitoring disabled

#### Total Usage (1 to 100)

Specify the threshold for the usage rate of the Java heap areas used by the target Java VM.

Default: 80[%]

#### **Eden Space (1 to 100)**

Specify the threshold for the usage rate of the Java Eden Space used by the target Java VM. If G1 GC is specified as the GC method, read it as G1 Eden Space.

Default: 100[%]

#### **Survivor Space (1 to 100)**

Specify the threshold for the usage rate of the Java Survivor Space used by the target Java VM. If G1 GC is specified as the GC method, read it as G1 Survivor Space.

Default: 100[%]

#### **Tenured Gen (1 to 100)**

Specify the threshold for the usage rate of the Java Tenured(Old) Gen area used by the target Java VM. If G1 GC is specified as the GC method, read it as G1 Old Gen.

Default: 80[%]

#### **Monitor Non-Heap Memory Rate**

Enables the monitoring of the usage rates of the Java non-heap areas used by the target Java VM.

- When the check box is selected (default):  
Monitoring enabled
- When the check box is not selected:  
Monitoring disabled

#### **Total Usage (1 to 100)**

Specify the threshold for the usage rate of the Java non-heap areas used by the target Java VM.

Default: 80[%]

#### **Code Cache (1 to 100)**

Specify the threshold for the usage rate of the Java Code Cache area used by the target Java VM.

Default: 100[%]

#### **Perm Gen (1 to 100)**

Specify the threshold for the usage rate of the Java Perm Gen area used by the target Java VM.

Default: 80[%]

#### **Perm Gen[shared-ro] (1 to 100)**

Specify the threshold for the usage rate of the Java Perm Gen [shared-ro] area used by the target Java VM.

The **Java Perm Gen [shared-ro]** area is used when -client -Xshare:on -XX:+UseSerialGC is specified as the startup option of the target Java VM.

Default: 80[%]

#### **Perm Gen[shared-rw] (1 to 100)**

Specify the threshold for the usage rate of the Java Perm Gen [shared-rw] area used by the target Java VM.

The **Java Perm Gen [shared-rw]** area is used when -client -Xshare:on -XX:+UseSerialGC is specified as the startup option of the target Java VM.

Default: 80[%]

**Command** (within 255 bytes)

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)

`"/usr/local/bin/command" arg1 arg2`

Specify the commands that will be executed if errors are detected in the process for checking the amount of the usage of the Java heap area, Java non-heap area in the monitor target Java VM.

See "*Executing a command corresponding to cause of each detected error*".

Default: None

**Initialize**

Click **Initialize** to set all the items to their default values.

**4.43.25 Memory tab (when Oracle Java(usage monitoring) is selected for JVM Type)**

**JVM Monitor Resource Tuning Properties**

**Monitor Heap Memory Usage**

Enables the monitoring of the usage rates of the Java heap areas used by the target Java VM.

- When the check box is selected:  
Monitoring is enabled.
- When the check box not selected (default):  
Monitoring is disabled.

**Total Usage** (0 to 102400)

Specify the threshold for the usage rates of the Java heap areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

**Eden Space** (0 to 102400)

Specify the threshold for the usage rate of the Java Eden Space used by the target Java VM. If zero is specified, this item is not monitored. If G1 GC is specified as the GC method, read it as G1 Eden Space.

Default: 0[MB]

**Survivor Space** (0 to 102400)

Specify the threshold for the usage rate of the Java Survivor Space used by the target Java VM. If zero is specified, this item is not monitored. If G1 GC is specified as the GC method, read it as G1 Survivor Space.

Default: 0[MB]

**Tenured Gen** (0 to 102400)

Specify the threshold for the usage rate of the Java Tenured(Old) Gen area used by the target Java VM. If zero is specified, this item is not monitored. If G1 GC is specified as the GC method, read it as G1 Old Gen.

Default: 0[MB]

**Monitor Non-Heap Memory Usage**

Enables the monitoring of the usage rate of the Java non-heap areas used by the target Java VM.

- When the check box is selected:  
Monitoring is enabled.
- When the check box is not selected (default):  
Monitoring is disabled.

**Total Usage** (0 to 102400)

Specify the threshold for the usage rate of the Java non-heap areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

**Code Cache** (0 to 102400)

Specify the threshold for the usage rate of the Java Code Cache area used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

**CodeHeap non-nmethods** (0 to 102400)

Specify the threshold for the usage rate of the Java CodeHeap non-nmethods areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

**CodeHeap profiled** (0 to 102400)

Specify the threshold for the usage rate of the Java CodeHeap profiled nmethods areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

**CodeHeap non-profiled** (0 to 102400)

Specify the threshold for the usage rate of the Java CodeHeap non-profiled nmethods areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

#### Compressed Class Space (0 to 102400)

Specify the threshold for the usage rate of the Compressed Class Space areas used by the target Java VM. If zero is specified, this item is not monitored.

Default: 0[MB]

#### Metaspace (0 to 102400)

Specify the threshold for the usage rate of the Metaspace area used by the target Java VM.

Default: 0[MB]

#### Command (within 255 bytes)

Specify the command to execute if an error is detected in the target Java VM. It is possible to specify the command to execute for each error cause, as well as arguments. Specify a full path. Enclose an executable file name with double quotes (""). Example) "/usr/local/bin/command" arg1 arg2

Specify the commands that will be executed if errors are detected in the process for checking the amount of the usage of the Java heap area, Java non-heap area in the monitor target Java VM.

See also "*Executing a command corresponding to cause of each detected error*".

Default: None

#### Initialize

Click the **Initialize** button to set all the items to their default values.

### 4.43.26 Memory tab (when Oracle JRockit is selected for JVM Type)

Enables the monitoring of the usage rates of the Java heap areas used by the target Java VM.

- When the check box is selected (default):

Monitoring enabled

- When the check box is not selected:  
Monitoring disabled

**Total Usage (1 to 100)**

Specify the threshold for the usage rate of the Java heap areas used by the target Java VM.

Default: 80[%]

**Nursery Space (1 to 100)**

Specify the threshold for the usage rate of the Java Nursery Space used by the target JRockit JVM.

Default: 80[%]

**Old Space (1 to 100)**

Specify the threshold for the usage rate of the Java Old Space used by the target JRockit JVM.

Default: 80[%]

**Monitor Non-Heap Memory Rate**

Enables the monitoring of the usage rates of the Java non-heap areas used by the target Java VM.

- When the check box is selected (default):  
Monitoring enabled
- When the check box is not selected:  
Monitoring disabled

**Total Usage (1 to 100)**

Specify the threshold for the usage rate of the Java non-heap areas used by the target Java VM.

Default: 80[%]

**Class Memory (1 to 100)**

Specify the threshold for the usage rate of the Java Class Memory used by the target JRockit JVM.

Default: 100[%]

**Command** (within 255 bytes)

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)

`"/usr/local/bin/command" arg1 arg2`

Specify the commands that will be executed if errors are detected in the process for checking the amount of the usage of the Java heap area, Java non-heap area in the monitor target Java VM.

See "*Executing a command corresponding to cause of each detected error*".

Default: None

**Initialize**

Click **Initialize** to set all the items to their default values.

### 4.43.27 Thread tab

The screenshot shows the 'JVM Monitor Resource Tuning Properties' dialog with the 'Thread' tab selected. The 'Monitor the number of Active Threads' checkbox is unchecked. The value '65535' is entered in the text field next to it. The 'Command' text area is empty. The 'Initialize' button is visible. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

#### Monitor the number of Active Threads (1 to 65535)

Specify the upper limit threshold for the number of threads running on the monitor target Java VM.

Default: 65535 [threads]

#### Command (within 255 bytes)

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)

`"/usr/local/bin/command" arg1 arg2`

Specify the commands that will be executed if errors are detected in the process for checking the number of active threads in the monitor target Java VM.

See *"Executing a command corresponding to cause of each detected error"*.

Default: None

#### Initialize

Click **Initialize** to set all the items to their default values.

### 4.43.28 GC tab

The screenshot shows the 'JVM Monitor Resource Tuning Properties' dialog with the 'GC' tab selected. The 'Monitor the time in Full GC' checkbox is unchecked, with '65535' in the adjacent text field and 'msec' to its right. The 'Monitor the count of Full GC execution' checkbox is checked, with '1' in the adjacent text field and 'count' to its right. The 'Command' text area is empty. The 'Initialize' button is visible. At the bottom right are 'OK', 'Cancel', and 'Apply' buttons.

#### Monitor the time in Full GC (1 to 65535)

Specify the threshold for the Full GC execution time since previous measurement on the target Java VM. The threshold for the Full GC execution time is the average obtained by dividing the Full GC execution time by the number of times Full GC occurs since the previous measurement.

To determine the case in which the Full GC execution time since the previous measurement is 3000 milliseconds and Full GC occurs three times as an error, specify 1000 milliseconds or less.

Default: 65535 [milliseconds]

#### **Monitor the count of Full GC execution (1 to 65535)**

Specify the threshold for the number of times Full GC occurs since previous measurement on the target Java VM.

Default: 1 (time)

#### **Command (within 255 bytes)**

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)  
"/usr/local/bin/command" arg1 arg2

Specify the commands that will be executed if errors are detected in the process for measuring time in Full GC and the count of Full GC execution in the monitor target Java VM.

See "*Executing a command corresponding to cause of each detected error*".

Default: None

#### **Initialize**

Click **Initialize** to set all the items to their default values.

### 4.43.29 WebLogic tab

JVM Monitor Resource Tuning Properties

Memory Thread GC **WebLogic** Load Balancer Linkage

**Monitor the requests in Work Manager**

☒ Increment from the last  %

**Monitor the requests in Thread Pool**
☒

**Waiting Requests**

☐ The number

☐ Average

☒ Increment from the last  %

**Executing Requests**

☐ The number

☐ Average

☒ Increment from the last  %

**Command**

Displayed only when **WebLogic Server** is selected for **Target**.

#### Monitor the requests in Work Manager

Enables the monitoring of the wait requests by Work Managers on the WebLogic Server.

- When the check box is selected:  
Monitoring enabled
- When the check box is not selected (default):  
Monitoring disabled

#### Target Work Managers

Specify the names of the Work Managers for the applications to be monitored on the target WebLogic Server. To monitor Work Managers, you must specify this setting.

*App1[WM1,WM2,...];App2[WM1,WM2,...];...*

*For App and WM, only ASCII characters are valid (except Shift\_JIS codes 0x005C and 0x00A1 to*

0x00DF).

To specify an application that has an application archive version, specify "application\_name#version" in *App*.

When the name of the application contains "[" and/or "]", prefix it with "\ \".

(Ex.) When the application name is app[2], enter app\\[2\\].

Default: None

#### **The number (1 to 65535)**

Specify the threshold for the wait request count for the target WebLogic Server Work Manager(s).

Default: 65535

#### **Average (1 to 65535)**

Specify the threshold for the wait request count average for the target WebLogic Server Work Manager(s).

Default: 65535

#### **Increment from the last (1 to 1024)**

Specify the threshold for the wait request count increment since the previous measurement for the target WebLogic Server Work Manager(s).

Default: 80[%]

#### **Monitor the requests in Thread Pool**

In WebLogic Server thread pool to be monitored, the number of wait requests, and the monitoring settings of the number of executing request. The number of requests, HTTP requests and the number that was waiting to be processed and run inside WebLogic Server, and includes the number of requests of the processing performed by the internal EJB call and WebLogic Server. However, it can not judge an abnormal state to be increased. Please specify if you want to the collection of JVM statistics log.

- When the check box is selected (default):  
Monitoring enabled
- When the check box is not selected:  
Monitoring disabled

#### **Waiting Requests The number (1 to 65535)**

Specify the threshold for the wait request count.

Default: 65535

#### **Waiting Requests Average (1 to 65535)**

Specify the threshold for the wait request count average.

Default: 65535

#### **Waiting Requests Increment from the last (1 to 1024)**

Specify the threshold for the wait request count increment since the previous measurement.

Default: 80[%]

#### **Executing Requests The number (1 to 65535)**

Specify the threshold for the number of requests executed per unit of time.

Default: 65535

#### **Executing Requests Average (1 to 65535)**

Specify the threshold for the average count of requests executed per unit of time.

Default: 65535

#### Executing Requests Increment from the last (1 to 1024)

Specify the threshold for the increment of the number of requests executed per unit of time since the previous measurement.

Default: 80[%]

#### Command (within 255 bytes)

Specify the commands that will be executed if errors in the monitor target Java VM are detected. A specific command and argument(s) can be specified for each error cause. Use an absolute path to specify each command. Place the executable file name in double quotes (") to specify it. Example)

"/usr/local/bin/command" arg1 arg2

Specify the commands that will be executed if errors are detected in the process for executing requests in the Work Manager and Thread Pool of WebLogic Server.

See "*Executing a command corresponding to cause of each detected error*".

Default: None

#### Initialize

Click **Initialize** to set all the items to their default values.

### 4.43.30 Load Balancer Linkage tab

The screenshot shows a dialog box titled "JVM Monitor Resource Tuning Properties". It has five tabs: "Memory", "Thread", "GC", "WebLogic", and "Load Balancer Linkage". The "Load Balancer Linkage" tab is selected. Below the tabs, there is a section titled "Load calculation function of target Java VM". Under this section, there is a label "Memory Pool Monitor" followed by an unchecked checkbox. At the bottom left of the dialog is an "Initialize" button. At the bottom right are "OK", "Cancel", and "Apply" buttons.

This screen appears when an item other than **BIG-IP LTM** is selected as the load balancer type.

#### Memory Pool Monitor

Enables the monitoring of the memory pool when notifying the load balancer of dynamic load information.

- When the check box is selected:  
Monitoring enabled
- When the check box is not selected (default):  
Monitoring disabled

#### Initialize

Click the **Initialize** button to set all the items to their default values.

### 4.43.31 Load Balancer Linkage tab

The screenshot shows a dialog box titled "JVM Monitor Resource Tuning Properties". It has five tabs: "Memory", "Thread", "GC", "WebLogic", and "Load Balancer Linkage". The "Load Balancer Linkage" tab is selected. Below the tabs, there are three sections: "Load calculation function of target Java VM" with a "Memory Pool Monitor" checkbox (unchecked); "Control of distributed nodes" with a "Cut off an obstacle node dynamically" checkbox (unchecked); and "Restart Command" with a text input field and a "Timeout" field set to "3600" with a "sec" label. There is an "Initialize" button on the left and "OK", "Cancel", and "Apply" buttons on the right.

This screen appears when **BIG-IP LTM** is selected as the load balancer type.

#### Memory Pool Monitor

Enables the monitoring of the memory pool when notifying the load balancer of dynamic load information.

- When the check box is selected:  
Monitoring enabled
- When the check box is not selected (default):  
Monitoring disabled

#### Cut off an obstacle node dynamically

When the JVM monitor detects a monitor target failure (example: the collection information exceeds the configured threshold), it sets whether to update the status of the BIG-IP LTM distributed node from "enable" to "disable."

- When the check box is selected:  
Update the status from enable to disable.
- When the check box is not selected (default):  
Do not update.

#### Restart Command

Specify the absolute path of the command to be executed after waiting until the number of connections of the distributed node becomes 0. This function is effective when the monitor target is restarted when resident monitoring is performed and a monitor target failure is detected. Specify the same value between JVM monitor resources.

#### Timeout (0 to 2592000)

After updating the distributed node status from "enable" to "disable," the JVM monitor sets the timeout used when waiting until the number of connections of the distributed node falls to 0. If the timeout elapses, **[Restart Command]** is not executed.

Default: 3600 [sec]

### **Initialize**

Click the **Initialize** button to set **Memory Pool Monitor**, **Cut off an obstacle node dynamically**, and **Timeout** to their default values.

## 4.44 Understanding System monitor resources

System monitor resources periodically collect statistical information about System resources analyze the information according to given knowledge data. System monitor resources serve to detect the exhaustion of resources early according to the results of analysis.

### 4.44.1 Notes on System monitor resource

To use a System monitor resource, zip and unzip packages must have been installed on the servers.

For the supported versions of System Resource Agent, see "Applications supported by monitoring options" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

For the recovery target, specify the resource to which fail-over is performed upon the detection of an error in resource monitoring by System Resource Agent.

The use of the default System Resource Agent settings is recommended.

Errors in resource monitoring may be undetectable when:

- A value repeatedly exceeds and then falls below a threshold during whole system resource monitoring.

If the date or time of the OS has been changed while System Resource Agent is running, resource monitoring may operate incorrectly as described below because the timing of analysis which is normally done at 10 minute intervals may differ the first time after the date or time is changed. If either of the following occur, suspend and resume cluster.

- No error is detected even after the specified duration for detecting errors has passed.
- An error is detected before the specified duration for detecting errors has elapsed.

Once the cluster has been suspended and resumed, the collection of information is started from that point of time.

For the SELinux setting, set permissive or disabled.

The enforcing setting may disable the communication needed by EXPRESSCLUSTER.

The amount of system resources used is analyzed at 10-minute intervals. Thus, an error may be detected up to 10 minutes after the monitoring session.

The amount of disk resources used is analyzed at 60-minute intervals. Thus, an error may be detected up to 60 minutes after the monitoring session.

Specify a value smaller than the actual disk size when specifying the disk size for free space monitoring of a disk resource. If a value is specified that is larger than the actual disk size, an error will be detected due to insufficient free space.

If the monitored disk has been replaced, analyzed information up until the time of the disk replacement will be cleared if one of the following items of information differs between the previous and current disks.

- Total disk capacity
- File system

Disk resource monitoring can only monitor disk devices.

For server for which no swap was allocated, uncheck the monitoring of total virtual memory usage.

Disk usage information collected by System Resource Agent is calculated by using the total disk space and free disk space. This value may slightly differ from the disk usage which df(1) command shows because it uses a different calculation method.

Up to 64 disk units can be simultaneously monitored by the disk resource monitoring function.

If **System monitor** is not displayed in the **Type** column on the monitor resource definition screen, select **Get License Info** and then acquire the license information.

System monitor resource collected statistics information and analysis information, it outputs. When the number of these files reached following biggest number, it's eliminated from an old file.

(<data pass> in following text is "<EXPRESSCLUSTER\_install\_path >/ha/sra/data/".)

- Statistical information data of system resources.  
Path: <data path>/hasrm\_monitor\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 1500
- Analyzed information data of system resources.  
Path: <data path>/hasrm\_analyze\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 3
- Statistical information data of disk resources.  
Path: <data path>/hasrm\_diskcapacity\_monitor\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 10
- Analyzed information data of disk resources.  
Path: <data path>/hasrm\_diskcapacity\_analyze\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 3

#### 4.44.2 How System monitor resources perform monitoring

System monitor resources monitor the following:

Periodically collect the amounts of system resources and disk resources used and then analyze the amounts.

An error is recognized if the amount of a resource used exceeds a pre-set threshold.

When an error detected state persists for the monitoring duration, it is posted as an error detected during resource monitoring.

System resource monitoring with the default values reports an error found in resource monitoring 60 minutes later if the resource usage does not fall below 90%.

The following shows an example of error detection for the total memory usage in system resource monitoring with the default values.

- The total memory usage remains at the total memory usage threshold or higher as time passes, for at least a certain duration of time.

Fig. 4.83: Total memory usage at its threshold or higher for a certain time, which leads to error detection

- The total memory usage rises and falls in the vicinity of the total memory usage threshold as time passes, but always remains under that threshold.

In the following figure, the total memory usage temporarily reaches its threshold (90%) or higher. However, this situation does not last for the monitoring duration (60 minutes), and therefore does not lead to detecting an error in the total memory usage.

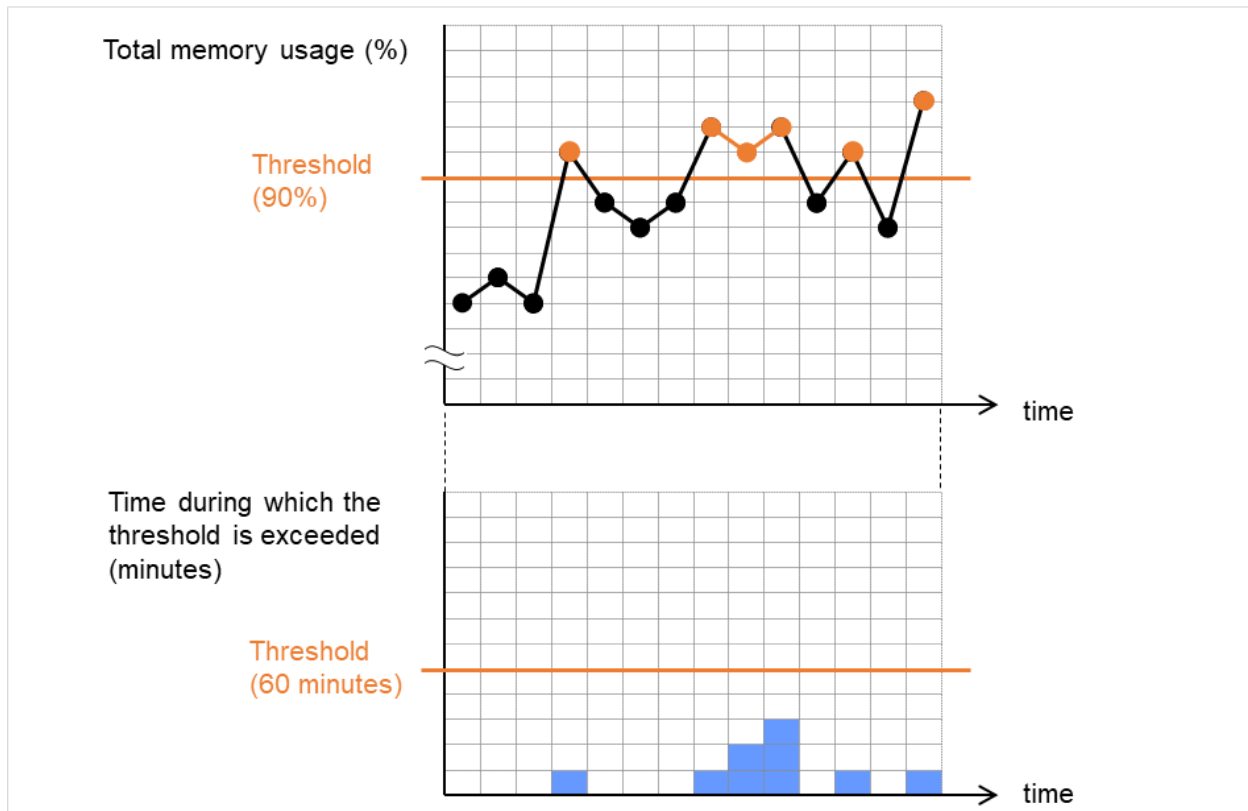

Fig. 4.84: Total memory usage at its threshold or higher for less than a certain time, which does not lead to error detection

If disk resource monitoring operated under the default settings, it will report a notice level error after 24 hours.

The following chart describes how disk resource monitoring detects disk usage errors when operating under the default settings.

#### Monitoring disk usage by warning level

- In the following example, disk usage exceeds the threshold which is specified as the warning level upper limit. This excess causes an error to be considered to occur in monitoring the disk usage.

Fig. 4.85: Disk usage exceeding the upper limit of the warning level, which leads to error detection

- In the following example, disk usage increases and decreases within certain range, and does not exceed the threshold which is specified as the warning level upper limit.

Fig. 4.86: Disk usage not exceeding the upper limit of the warning level, which does not lead to error detection

#### Monitoring disk usage by notice level

- In the following example, disk usage continuously exceeds the threshold specified as the notification level upper limit, and the duration exceeds the set length.

The excess of disk usage causes an error to be considered to occur in monitoring the disk usage.

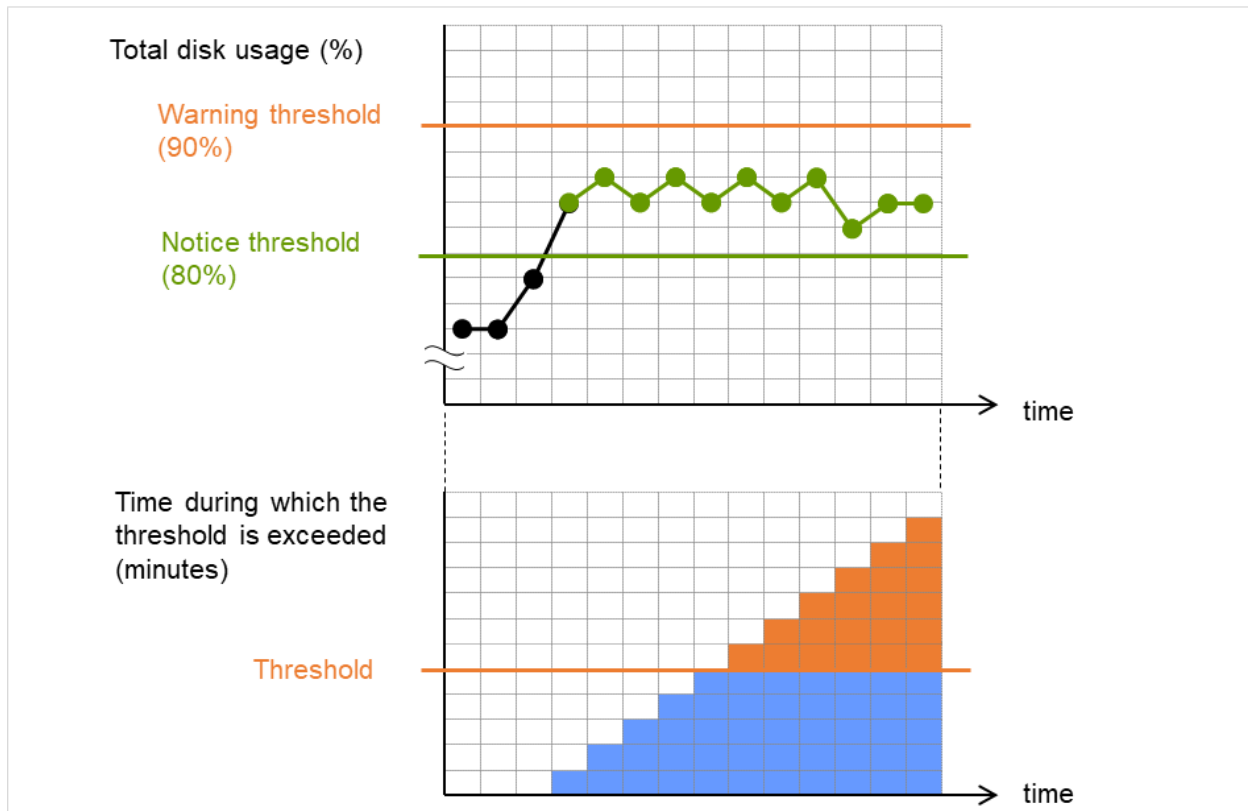

Fig. 4.87: Disk usage exceeding the upper limit of the notification level for a certain time, which leads to error detection

- In the following example, disk usage increases and decreases within a certain range, and does not exceed the threshold specified as the notification level upper limit.

Since the excess of disk usage does not last for a certain time, no error is considered to occur in monitoring the disk usage.

Fig. 4.88: Disk usage exceeding the upper limit of the notification level for less than a certain time, which does not lead to error detection

#### Monitoring CPU usage

Enables CPU usage monitoring.

- When the check box is selected:  
Monitoring is enabled for the CPU usage.
- When the check box is not selected:  
Monitoring is disabled for the CPU usage.

#### **CPU usage (1 to 100)**

Specify the threshold for the detection of the CPU usage.

#### **Duration Time (1 to 1440)**

Specify the duration for detecting the CPU usage.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

#### **Monitoring total usage of memory**

Enables the monitoring of the total usage of memory.

- When the check box is selected:  
Monitoring is enabled for the total usage of memory.
- When the check box is not selected:  
Monitoring is disabled for the total usage of memory.

#### **Total usage of memory (1 to 100)**

Specify the threshold for the detection of a memory use amount error (percentage of the memory size implemented on the system).

#### **Duration Time (1 to 1440)**

Specify the duration for detecting a total memory usage error.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

#### **Monitoring total usage of virtual memory**

Enables the monitoring of the total **usage of virtual memory**.

- When the check box is selected:  
Monitoring is enabled for the total **usage of virtual memory**.
- When the check box is not selected:  
Monitoring is disabled for the total **usage of virtual memory**.

#### **Total usage of virtual memory (1 to 100)**

Specify the threshold for the detection of a virtual memory usage error.

#### **Duration Time (1 to 1440)**

Specify the duration for detecting a total virtual memory usage error.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

#### **Monitoring total number of opening files**

Enables the monitoring of the total number of **opening** files.

- When the check box is selected:  
Monitoring is enabled for the total number of **opening** files.

- When the check box is not selected:  
Monitoring is disabled for the total number of opening files.

**Total number of opening files (in a ratio comparing with the system upper limit) (1 to 100)**

Specify the threshold for the detection of an error related to the total number of opening files (percentage of the system upper limit).

**Duration Time (1 to 1440)**

Specify the duration for detecting an error with the total number of opening files.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

**Monitoring total number of running threads**

Enables the monitoring of the total number of running threads.

- When the check box is selected:  
Monitoring is enabled for the total number of running threads.
- When the check box is not selected:  
Monitoring is disabled for the total number of running threads.

**Total number of running threads (1 to 100)**

Specify the threshold for the detection of an error related to the total number of running threads (percentage of the system upper limit).

**Duration Time (1 to 1440)**

Specify the duration for detecting an error with the total number of running threads.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

**Monitoring number of running processes of each user**

Enables the monitoring of the number of processes being run **of each user**

- When the check box is selected:  
Monitoring is enabled for the number of processes being run **of each user**.
- When the check box is not selected:  
Monitoring is disabled for the number of processes being run **of each user**.

**Number of running processes of each user (1 to 100)**

Specify the threshold for the detection of an error related to the number of processes being run **of each user** (percentage of the system upper limit).

**Duration Time (1 to 1440)**

Specify the duration for detecting an error with the number of processes being run **of each user**.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

**Add**

Click this to add disks to be monitored. The **Input of watch condition** dialog box appears.

Configure the detailed monitoring conditions for error determination, according to the descriptions given in the **Input of watch condition** dialog box.

**Remove**

Click this to remove a disk selected in **Disk List** so that it will no longer be monitored.

### Edit

Click this to display the **Input of watch condition** dialog box. The dialog box shows the monitoring conditions for the disk selected in **Disk List**. Edit the conditions and click **OK**.

**Mount point** (within 1024 bytes)

Set the mountpoint to be monitored. The name must begin with a forward slash (/).

### Utilization rate

Enables the monitoring of the disk usage.

- When the check box is selected:  
Monitoring is enabled for the disk usage.
- When the check box is not selected:  
Monitoring is disabled for the disk usage.

### Warning level (1 to 100)

Specify the threshold for warning level error detection for disk usage.

### Notice level (1 to 100)

Specify the threshold for notice level error detection for disk usage.

**Duration Time (1 to 43200)**

Specify the duration for detecting a notice level error of the disk usage rate.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

**Free space**

Enables the monitoring of the free disk space.

- When the check box is selected:  
Monitoring is enabled for the free disk space.
- When the check box is not selected:  
Monitoring is disabled for the free disk space.

**Warning level (1 to 4294967295)**

Specify the amount of disk space (in megabytes) for which the detection of an free disk space error at the warning level is recognized.

**Notice level (1 to 4294967295)**

Specify the amount of disk space (in megabytes) for which the detection of an free disk space error at the notice level is recognized.

**Duration Time (1 to 43200)**

Specify the duration for detecting a notice level error related to the free disk space.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

## 4.45 Understanding Process resource monitor resources

Process resource monitor resources periodically collect statistical information about resources used by processes and analyze the information according to given knowledge data. Process resource monitor resources serve to detect the exhaustion of resources early according to the results of analysis.

### 4.45.1 Notes on Process resource monitor resource

To use a Process resource monitor resource, zip and unzip packages must have been installed on the servers.

For the supported versions, see "Applications supported by monitoring options" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

For the recovery target, specify the resource to which fail-over is performed upon the detection of an error in resource monitoring by Process resource monitor resource.

The use of the default Process resource monitor resource settings is recommended.

Swapped out processes are not subject to the detection of resource errors.

If the date or time of the OS has been changed while System Resource Agent is running, resource monitoring may operate incorrectly as described below because the timing of analysis which is normally done at 10 minute intervals may differ the first time after the date or time is changed.

If either of the following occur, suspend and resume cluster.

- No error is detected even after the specified duration for detecting errors has passed.
- An error is detected before the specified duration for detecting errors has elapsed.

Once the cluster has been suspended and resumed, the collection of information is started from that point of time.

For the SELinux setting, set permissive or disabled.

The enforcing setting may disable the communication needed by EXPRESSCLUSTER.

The amount of process resources used is analyzed at 10-minute intervals. Thus, an error may be detected up to 10 minutes after the monitoring session.

If **Process resource monitor resource** is not displayed in the **Type** column on the monitor resource definition screen, select **Get License Info** and then acquire the license information.

For information on the licenses necessary for process resource monitor resources, see "Function list and necessary license" in "Designing a system configuration" in "Notes and Restrictions" in the "Getting Started Guide".

Process resource monitor resource collected statistics information and analysis information, it outputs. When the number of these files reached following biggest number, it's eliminated from an old file.

(<data path> in following text is "<EXPRESSCLUSTER\_install\_path >/ha/sra/data/".)

- Statistical information data of process resources.  
Path: <data path>/hasrm\_monitor\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 1500
- Analyzed information data of system resources.  
Path: <data path>/hasrm\_analyze\_list.xml.YYYYMMDDhhmmss.zip  
Maximum number of a file: 3

To return the status of the process resource monitor resource from error to normal, perform either of the following:

- Suspending and resuming the cluster
- Stopping and starting the cluster

## 4.45.2 How Process resource monitor resources perform monitoring

Process resource monitor resources monitor the following:

Periodically collect the amounts of process resources used and then analyze the amounts.

An error is recognized if the amount of a resource used exceeds a pre-set threshold.

When an error detected state persists for the monitoring duration, it is posted as an error detected during resource monitoring.

If process resource monitoring (of the CPU, memory, number of opening files, or number of zombie processes) operated by using the default values, a resource error is reported after 24 hours.

The following chart describes how process resource monitoring detects memory usage errors.

- In the following example, as time progresses, memory usage increases and decreases, the maximum value is updated more times than specified, and increases by more than 10% from its initial value.

The specified update count of the maximum value is exceeded, the increasing rate exceeds its initial value (10%), and then the default period (24 hours) elapses. This causes a memory leak to be considered to occur.

Fig. 4.89: Regarding memory usage, the maximum value is updated more times than specified, and the increasing rate exceeds its initial value (10%), which leads to error detection

- In the following example, memory usage increases and decreases, but remains within a set range.

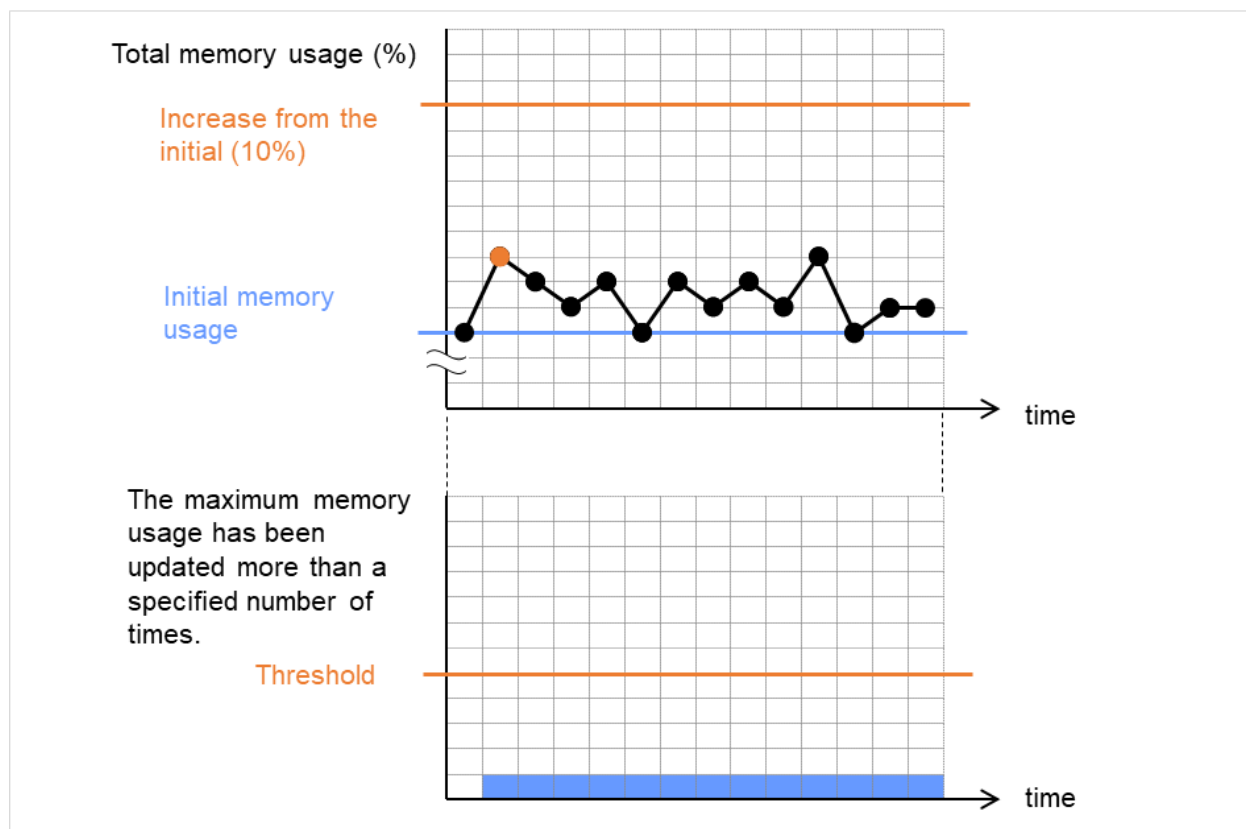

Fig. 4.90: Memory usage increasing/decreasing within a set range, which does not lead to error detection

Process Name (within 1023 bytes)

Set the name of the target process. Without setting it, all started processes are monitored.

Wild cards can be used to specify a process name by using one of the following three patterns. No other wild card pattern is permitted.

[prefix search] <string included in the process name>\*

[suffix search] \*<string included in the process name>

[partial search] \*<string included in the process name>\*

Up to 1023 bytes can be specified for the monitor target process name. To specify a monitor target process with a name that exceeds 1023 bytes, use a wildcard (such as \*).

If the name of the target process is 1024 bytes or longer, only the first 1023 bytes can be recognized as the process name. If you use a wild card (such as \*) to specify a process name, specify a string containing the first 1024 or fewer bytes.

Check the monitor target process name which is actually running by ps(1) command, etc, and specify the monitor target process name.

- Execution result

UID	PID	PPID	C	STIME	TTY	TIME	CMD
root	1	0	0	Sep12	?	00:00:00	init [5]
:							
root	5314	1	0	Sep12	?	00:00:00	/usr/sbin/acpid
root	5325	1	0	Sep12	?	00:00:00	/usr/sbin/sshd
htt	5481	1	0	Sep12	?	00:00:00	/usr/sbin/htt -retryonerror 0

From the above command result, /usr/sbin/htt -retryonerror 0 is specified as monitor target process name in the case of monitoring /usr/sbin/htt.

The process name specified for the name of the target process specifies the target process, using the process arguments as part of the process name. To specify the name of the target process, specify the process name containing the arguments. To monitor only the process name with the arguments excluded, specify it with the wildcard (\*) using right truncation or partial match excluding the arguments.

### Monitoring CPU usage

Enables CPU usage monitoring.

- When the check box is selected:  
Monitoring is enabled for the CPU usage.
- When the check box is not selected:  
Monitoring is disabled for the CPU usage.

#### CPU usage (1 to 100)

Specify the threshold for the detection of the CPU usage.

#### Duration Time (1 to 129600)

Specify the duration for detecting the CPU usage.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

### Monitoring usage of memory

Enables the monitoring of the usage of memory.

- When the check box is selected:  
Monitoring is enabled for the total usage of memory.
- When the check box is not selected:  
Monitoring is disabled for the total usage of memory.

#### Rate of Increase from the First Monitoring Point (1 to 1000)

Specify the threshold for the detection of a memory use amount error.

#### Duration Time (1 to 129600)

Specify the duration for detecting a total memory usage error.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

### Monitoring number of opening files(maximum number)

Enables the monitoring of the number of opening files(maximum number).

- When the check box is selected:  
Monitoring is enabled for the number of opening files.
- When the check box is not selected:  
Monitoring is disabled for the number of opening files.

#### **Refresh Count (1 to 1024)**

Specify the refresh count for the detection of the number of opening files error.

If the number of opening files maximum value is updated more count than specified, the detection of an error is recognized.

#### **Monitoring number of opening files(kernel limit)**

Enables the monitoring of the number of opening files(kernel limit).

- When the check box is selected:  
Monitoring is enabled for the number of opening files.
- When the check box is not selected:  
Monitoring is disabled for the number of opening files.

#### **Ratio (1 to 100)**

Specify the ration for detection of the opening files(the percentage to the kernel limit).

#### **Monitoring number of running threads**

Enables the monitoring of the number of running threads.

- When the check box is selected:  
Monitoring is enabled for the number of running threads.
- When the check box is not selected:  
Monitoring is disabled for the number of running threads.

#### **Duration Time (1 to 129600)**

Specify the duration for detecting an error with the total number of running threads.

If the threshold is continuously exceeded over the specified duration, the detection of an error is recognized.

#### **Monitoring Zombie Process**

Enables the monitoring of Zombie Processes.

- When the check box is selected:  
Monitoring is enabled for the Zombie Processes.
- When the check box is not selected:  
Monitoring is disabled for the Zombie Processes.

#### **Duration Time (1 to 129600)**

Specify the duration for detecting Zombie Processes.

If process is a Zombie Process over the specified duration, the detection of an error is recognized.

#### **Monitoring Processes of the Same Name**

Enables the monitoring of Processes of the Same Name.

- When the check box is selected:  
Monitoring is enabled for the Processes of the Same Name.

- When the check box is not selected:  
Monitoring is disabled for the Processes of the Same Name.

**Count (1 to 10000)**

Specify the count for detecting an error with the processes of the same name.

If the processes of the same name has been exists more than specified numbers, the detection of an error is recognized.

## 4.46 Understanding AWS Elastic IP monitor resources

For EIP control, AWS Elastic IP monitor resources confirm the existence of EIPs by using the AWS CLI command.

### 4.46.1 Notes on AWS Elastic IP monitor resources

- AWS Elastic IP monitor resources are automatically created when AWS Elastic IP resources are added. A single AWS Elastic IP monitor resource is automatically created for a single AWS Elastic IP resource.
- See "Setting up AWS Elastic IP resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

### 4.46.2 Applying environment variables to AWS CLI run from the AWS Elastic IP monitor resource

See "Applying environment variables to AWS CLI run from the AWS Elastic IP resource" in "Understanding AWS Elastic IP resources" in "3. Group resource details" in this guide.

### 4.46.3 Monitor (special) tab

Info Monitor(common) **Monitor(special)** Recovery Action

Action when AWS CLI command failed to receive response\*

Disable recovery action(Do nothing) ▼

OK Cancel Apply

#### Action when AWS CLI command failed to receive response

Specify the action to be taken when acquiring the AWS CLI command response fails. This failure occurs, for example, when a region endpoint is down due to maintenance, when AWS CLI timeout occurs because of connection route troubles, heavy load or delay, or when a credential error occurs. Refer to the following instructions:

- Select **Enable recovery action** if you want to perform failover when AWS CLI command fails.
- Select **Disable recovery action(Display warning)** if you want to show a warning message without failover when AWS CLI command fails.
- Select **Disable recovery action(Do nothing)** if you think this error is CLI command failure (a monitoring target itself is in normal status) and no action needs to be taken. This option is recommended as still error detection can find EIP error (e.g. no EIP is found).

## 4.47 Understanding AWS Virtual IP monitor resources

For VIP control, AWS Virtual IP monitor resources confirm the existence of VIPs and the soundness of VPC routing by using the OS API and AWS CLI commands. AWS CLI command is executed for AWS Virtual IP monitor resources while monitoring to check the route table information.

### 4.47.1 Notes on AWS Virtual IP monitor resources

- AWS Virtual IP monitor resources are automatically created when AWS Virtual IP resources are added. A single AWS Virtual IP monitor resource is automatically created for a single AWS Virtual IP resource.
- See "Setting up AWS Virtual IP resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

### 4.47.2 Applying environment variables to AWS CLI run from the AWS Virtual IP monitor resource

See "*Applying environment variables to AWS CLI run from the AWS Virtual IP resource*" in "*Understanding AWS Virtual IP resources*" in "3. Group resource details" in this guide

#### Action when AWS CLI command failed to receive response

Specify the action to be taken when acquiring the AWS CLI command response fails. This failure occurs, for example, when a region endpoint is down due to maintenance, when AWS CLI timeout occurs because of connection route troubles, heavy load or delay, or when a credential error occurs. Refer to the following instructions:

- Select **Enable recovery action** if you want to perform failover when AWS CLI command fails.
- Select **Disable recovery action(Display warning)** if you want to show a warning message without failover when AWS CLI command fails.
- Select **Disable recovery action(Do nothing)** if you think this error is CLI command failure (a monitoring target itself is in normal status) and no action needs to be taken. This option is recommended as still error detection can find errors, for example when troubles are found in VPC routing condition or no VIP is found.

## 4.48 Understanding AWS AZ monitor resources

AWS AZ monitor resources monitor the soundness of the AZ to which each server belongs, by using the AWS CLI command. When the command result is available, AZ is in normal status. When information or impaired, AZ is in warning status. When unavailable, AZ is in error status. If you use internal version earlier than 4.2.0.1, only available represents the normal status (other results are categorized in error status).

### 4.48.1 Notes on AWS AZ monitor resources

- When monitoring an AZ, create a single AWS AZ monitor resource.
- See "Setting up AWS Elastic IP resources" and "Setting up AWS Virtual IP resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

### 4.48.2 Applying environment variables to AWS CLI run from the AWS AZ monitor resource

See "*Applying environment variables to AWS CLI run from the AWS Virtual IP resource*" in "*Understanding AWS Virtual IP resources*" in "3. Group resource details" in this guide.

This option is recommended as still error detection can find errors, for example when troubles are found in AZ condition.

## 4.49 Understanding AWS DNS monitor resources

AWS DNS monitor resources confirm the soundness of the registered IP address by using the OS API and AWS CLI commands.

Errors are detected when:

- The resource record set does not exist.
- The registered **IP Address** cannot be obtained by name resolution of the virtual host name (DNS name).

### 4.49.1 Notes on AWS DNS monitor resources

- AWS DNS monitor resources are automatically created when AWS DNS resources are added. A single AWS DNS monitor resource is automatically created for a single AWS DNS resource.
- See "Setting up AWS DNS resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" in the "Getting Started Guide".

### 4.49.2 Applying environment variables to AWS CLI run from the AWS DNS monitor resource

See "*Applying environment variables to AWS CLI run from the AWS DNS resource*" in "*Understanding AWS DNS resources*" in "3. Group resource details" in this guide.

## 4.50 Understanding Azure probe port monitor resources

Azure probe port monitor resources perform alive monitoring on a probe port control process that starts when Azure probe port resources are active on the node on which the Azure probe port resources are active. If the process does not start normally, a monitoring error occurs.

### 4.50.1 Notes on Azure probe port monitor resources

- Azure probe port monitor resources are automatically created when Azure probe port resources are added. One Azure probe port monitor resource is automatically created per Azure probe port resource.
- In Azure probe port monitor resources, I will monitor the occurrence of probe standby timeout on the Azure probe port resources. Therefore, **Interval** of Azure probe port monitor resource, than the value of the set in the Azure probe port resources monitored **Probe Wait Timeout**, you need to set a large value.
- See "Azure probe port resource settings" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".

### 4.50.2 Monitor (special) tab

Monitor Resource Properties | azureppw1 azureppw ✕

#### Action when Probe port wait timeout

Specify the recovery action to be taken when a probe port wait timeout occurs in Azure probe port resources.

## 4.51 Understanding Azure load balance monitor resources

Azure load balance monitor resources monitor to see if a port with the same port number as that of the probe port has been open on the node on which the Azure probe port resources are not active.

### 4.51.1 Note on Azure load balance monitor resources

- Azure load balance monitor resources are automatically created when Azure probe port resources are added. One Azure load balance monitor resource is automatically created per Azure probe port resource.
- See "Setting up Azure probe port resources" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".
- See "Setting up Azure load balance monitor resources" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".

### 4.51.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | azurelbw1" with a close button "azurelbw X". It has four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is selected. Inside this tab, there is a label "Target Resource\*" followed by a text input field containing "azurepp1" and a "Browse" button. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

#### Target Resource

Set Resource to be monitored

## 4.52 Understanding Azure DNS monitor resources

Azure DNS monitor resources issue a query to the authoritative DNS server and confirm the soundness of the registered IP address.

Errors are detected when:

- The registered IP Address cannot be obtained by name resolution of the virtual host name (DNS name).
- Failed to acquire the list of DNS servers.

### 4.52.1 Notes on Azure DNS monitor resources

- Azure DNS monitor resources are automatically created when Azure DNS resources are added. A single Azure DNS monitor resource is automatically created for a single Azure DNS resource.
- When using public DNS zone, charge occurs for registering the zone and query. Therefore, when **Check Name Resolution** is set to on, the charge occurs per **Interval**.
- See "Setting up Azure resources" in "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".

### 4.52.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | azurednsw1" with a close button "azurednsw X". Inside, there are four tabs: "Info", "Monitor(common)", "Monitor(special)", and "Recovery Action". The "Monitor(special)" tab is active. It contains a label "Check Name Resolution" followed by a checked checkbox. At the bottom right, there are three buttons: "OK", "Cancel", and "Apply".

#### Check Name Resolution

- The checkbox is selected. (default)  
Checks whether to obtain the registered IP address by name resolution of the virtual host name (DNS name).
- The checkbox is not selected.  
Monitoring disabled

## 4.53 Understanding Google Cloud Virtual IP monitor resources

Google Cloud Virtual IP monitor resources perform alive monitoring of nodes running Google Cloud Virtual IP resources about control processes which start to run when Google Cloud Virtual IP resources become active. If the process does not start properly, the system takes it as an error. Also, timeout on health check wait time may become an error depending on **Action when Health check wait timeout** settings.

### 4.53.1 Notes on Google Cloud Virtual IP monitor resources

- Google Cloud Virtual IP monitor resources are added automatically when you add Google Cloud Virtual IP resources. One Google Cloud Virtual IP monitor resource is created automatically for one Google Cloud Virtual IP resource.
- Google Cloud Virtual IP monitor resources check if timeout occurs or not on health check wait time in Google Cloud Virtual IP resources. Therefore the monitor interval values of Google Cloud Virtual IP monitor resources must be larger than the **Health check timeout** values set in the target Google Cloud Virtual IP resources.
- Refer to "Google Cloud Virtual IP resource settings" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".

### 4.53.2 Monitor (special) tab

Monitor Resource Properties | gcvipw1

#### Action when Health check wait timeout

Specifies actions when timeout of health check wait time occurs in Oracle Cloud Virtual IP resources.

## 4.57 Understanding Oracle Cloud load balance monitor resources

Oracle Cloud load balance monitor resources perform monitoring of nodes not running Oracle Cloud Virtual IP resources and check if the same port number of the health check port number opens.

### 4.57.1 Notes on Oracle Cloud load balance monitor resources

- Oracle Cloud load balance monitor resources are added automatically when you add Oracle Cloud Virtual IP resources. One Oracle Cloud load balance monitor resource is created automatically for one Oracle Cloud Virtual IP resource.
- Refer to "Setting up Oracle Cloud Virtual IP resources" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".
- Refer to "Setting up Oracle Cloud load balance monitor resources" on "Notes when creating EXPRESSCLUSTER configuration data" in "Notes and Restrictions" of the "Getting Started Guide".

### 4.57.2 Monitor (special) tab

The screenshot shows a window titled "Monitor Resource Properties | oclbw1". At the top right is a close button labeled "oclbw X". Below the title bar are four tabs: "Info", "Monitor(common)", "Monitor(special)" (which is the active tab), and "Recovery Action". In the "Monitor(special)" tab, there is a label "Target Resource\*" followed by a text input field containing "ocvip1". To the right of the input field is a "Browse" button. At the bottom right of the dialog are three buttons: "OK", "Cancel", and "Apply".

#### Target Resource

Specifies a name of the target Oracle Cloud Virtual IP resource.

## **HEARTBEAT RESOURCES DETAILS**

This chapter provides detailed information on heartbeat resources.

This chapter covers:

- *5.1. What are heartbeat resources?*
- *5.2. Understanding LAN heartbeat resources*
- *5.3. Understanding kernel mode LAN heartbeat resources*
- *5.4. Understanding disk heartbeat resources*
- *5.5. Understanding COM heartbeat resources*
- *5.6. Understanding BMC heartbeat resources*
- *5.7. Understanding Witness heartbeat resources*

## 5.1 What are heartbeat resources?

A server in a cluster configuration monitors whether the other server is being activated. For this monitoring, heartbeat resources are used.

1. LAN heartbeat/kernel mode LAN heartbeat (primary interconnect)

Fig. 5.1: LAN heartbeat/kernel mode LAN heartbeat (primary interconnect)

2. LAN heartbeat/kernel mode LAN heartbeat (secondary interconnect)

Fig. 5.2: LAN heartbeat/kernel mode LAN heartbeat (secondary interconnect)

3. Disk heartbeat

Fig. 5.3: Disk heartbeat

#### 4. COM heartbeat

Fig. 5.4: COM heartbeat

#### 5. BMC heartbeat

Fig. 5.5: BMC heartbeat

#### 6. Witness heartbeat

Fig. 5.6: Witness heartbeat

Heartbeat resource name	Abbreviation	Functional overview
LAN heartbeat resource (1)(2)	lanhb	Uses a LAN to monitor if servers are activated. Used for communication within the cluster as well.
Kernel mode LAN heartbeat resource (1)(2)	lankhb	A kernel mode module uses a LAN to monitor if servers are activated.
Disk heartbeat resource (3)	diskhb	Uses a dedicated partition in the shared disk to monitor if servers are activated.
COM heartbeat resource (4)	comhb	Uses a COM cable connecting two servers to monitor if servers are activated.
BMC heartbeat resource (5)	bmchb	Uses BMC to monitor whether servers are activated.
Witness heartbeat resource (6)	witnesshb	A module uses the Witness server to monitor whether or not servers are active

- At least either one LAN heartbeat resource or one kernel mode LAN heartbeat resource must be configured. It is recommended to set two or more LAN heartbeat resources resistant to a high system load be configured.
- Please make sure to set 1 or more LAN heartbeats or Kernel mode LAN heartbeats that can communicate among all the servers.
- When you configure the settings of interfaces for disk heartbeat and COM heartbeat resources, follow the specifications described below.

When a shared disk is used:	[Number of servers: up to 2] In principle, COM interface and disk interface [Number of servers: 3 or more] Disk interface
When a shared disk is not used:	[Number of servers: up to 2] COM interface

## **5.2 Understanding LAN heartbeat resources**

### **5.2.1 LAN heartbeat resources**

- You need to set at least one LAN heartbeat resource or kernel mode LAN heartbeat resource. It is recommended to have two or more LAN heartbeat resources; the one dedicated to interconnect and the one shared with interconnect and public.
- Communication data for alert synchronization is transmitted on an interface that is registered with the interconnect. You should consider network traffic when you configure the settings.

## 5.3 Understanding kernel mode LAN heartbeat resources

### 5.3.1 Environment where the kernel mode LAN heartbeat resources works

---

**Note:** This function is dependent on the distribution and kernel version. Refer to "Supported distributions and kernel versions" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide" before you configure the settings.

---

### 5.3.2 The settings of the kernel mode LAN heartbeat resources

With the kernel mode driver module, kernel mode LAN heartbeat resource offer similar functions that LAN heartbeats provide. The kernel mode LAN heartbeat resources have the following features.

- Kernel mode LAN heartbeat resource is less likely to be impacted by load of OS because it uses the kernel mode driver. This reduces the misinterpreting disconnect of interconnection.
- When used with the keepalive settings to watch user-mode monitor resource, the kernel mode LAN heartbeat resource allows reset to be recorded in other servers when the user mode stalling is detected.

### 5.3.3 kernel mode LAN heartbeat resources

- It is recommended to specify two or more kernel mode LAN heartbeat resources; the one dedicated to interconnect and the one shared with interconnect and public.

## 5.4 Understanding disk heartbeat resources

### 5.4.1 Setting the disk heartbeat resources

To use a heartbeat resource, you need to have the following settings.

- Allocate a dedicated partition on the shared disk. (You do not need to create any file system.)
- Configure settings that allow all servers to access the dedicated partition on the shared disk by the same device name.

When a disk heartbeat resource is being used, it can be checked if other servers are active even if the network is disconnected.

- (1) The figure below shows two servers connected to a shared disk.  
One of the partitions on the shared disk is used for the disk heartbeat.

Fig. 5.7: Disk heartbeat resource (1)

- (2) One of the network connections between the two servers is disconnected.

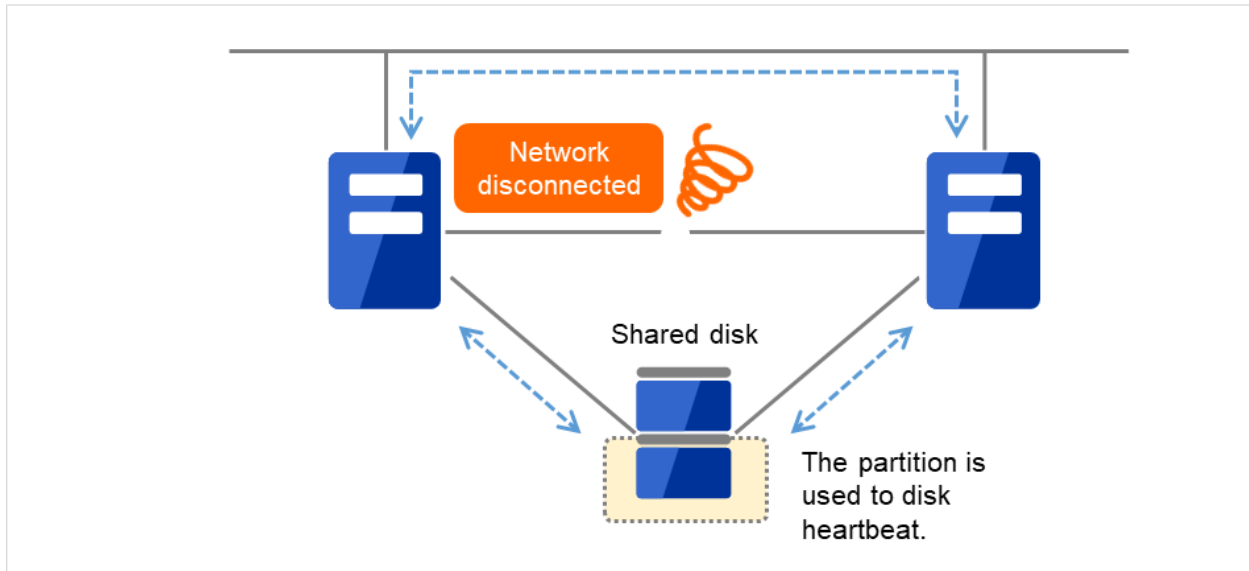

Fig. 5.8: Disk heartbeat resource (2)

- (3) Even if all the network connections between the two servers are disconnected, the disk heartbeat resource prevents the file system on the shared disk from being corrupted by a split brain syndrome.

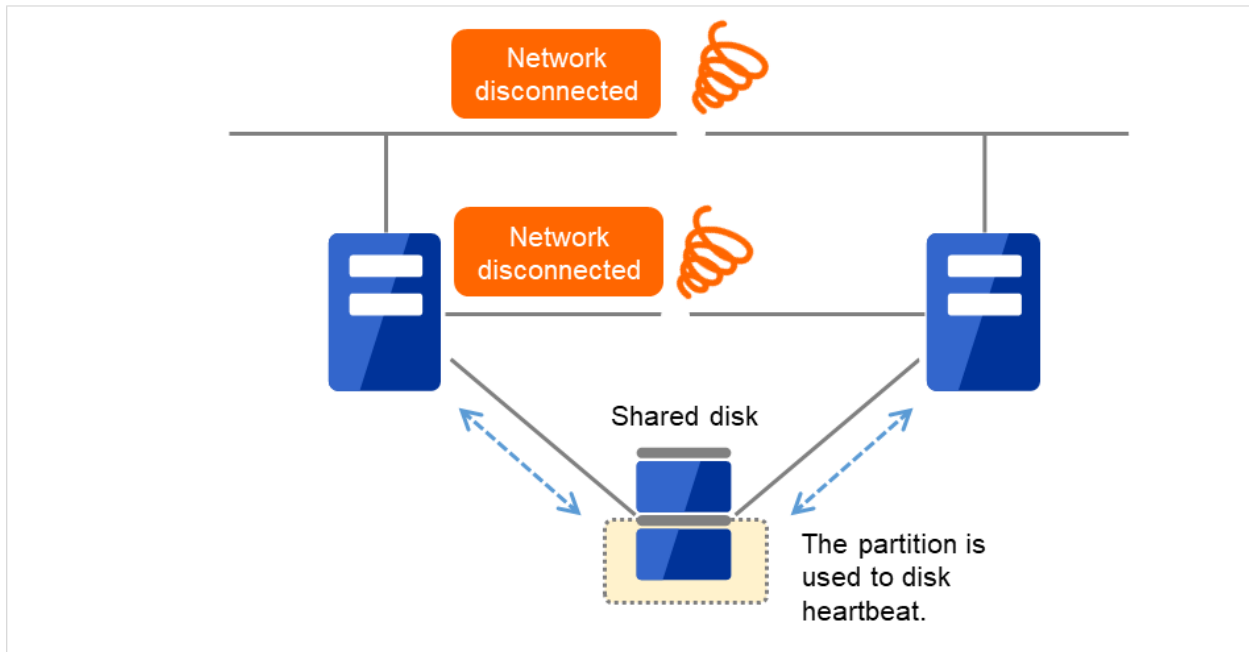

Fig. 5.9: Disk heartbeat resource (3)

If the cluster consists of three or more servers, you can have a configuration using a disk heartbeat resource as below. You can configure the settings that allow usage of the disk heartbeat resource only among the servers in the cluster using the shared disk.

For details, see "*Interconnect tab*" in "*Cluster properties*" in "*2. Parameter details*" in this guide.

Fig. 5.10: Configuration with a disk heartbeat resource (three servers)

### 5.4.2 Disk heartbeat resources

- It is recommended to use both a LAN heartbeat resource and a disk heartbeat resource when you use a shared disk.
- It is recommended to use one or two disk heartbeat resources in the cluster even if you are using two or more LUNs. You should consider how heavy the disk is loaded when you configure the settings because a disk heartbeat resource reads and/or writes to the disk every heartbeat interval.
- In each LUN, allocate a partition dedicated to a disk heartbeat. LUNs that do not use a disk heartbeat should also have a dummy partition because the file system can be damaged if device names are moved due to disk failure or other causes.

Partitions dedicated to disk heartbeat should have the same number across all the LUNs.

The figure below shows two storages, each of which contains four LUNs.

To each of the LUNs in the storages, a partition dedicated to a disk heartbeat is allocated. However, actually used is: the disk heartbeat partition on LUN 1-1 and that on LUN 2-1.

The other partitions, which are dedicated to a disk heartbeat for the other LUNs, are not actually used. These dummy partitions serve as substitutes in case the file system is damaged due to an unintentional change in the device name.

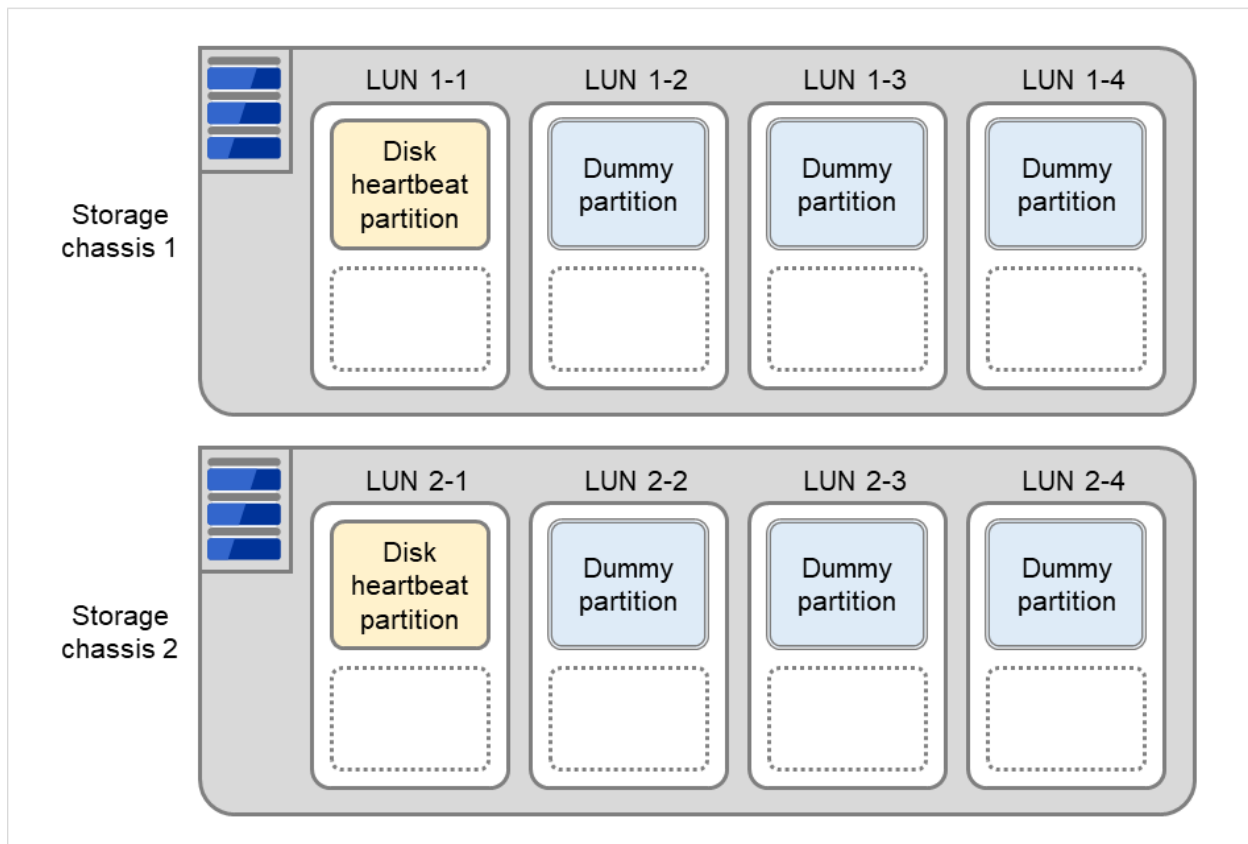

Fig. 5.11: Partition dedicated to a disk heartbeat

- Do not register to storage pool.

## **5.5 Understanding COM heartbeat resources**

### **5.5.1 Note on COM heartbeat resources**

It is recommended to use a COM heartbeat resource if your environments allows. This is because using a COM heartbeat resource prevents activating both systems when the network is disconnected.

## 5.6 Understanding BMC heartbeat resources

### 5.6.1 Notes on BMC heartbeat resources

BMC heartbeat resources provide functions similar to those of the LAN heartbeat resource. BMC heartbeat resources feature the following:

- Activation monitoring is performed with the hardware, and therefore is essentially unaffected by the load on the OS and is less likely to incorrectly recognize the disconnection of interconnects.
- The BMC hardware and firmware must support the BMC heartbeat. For the usable BMC versions, see "Servers supporting Express5800/A1080a" or Express5800/A1040a series -related functions" in "Hardware" in the "Getting Started Guide".

## 5.7 Understanding Witness heartbeat resources

### 5.7.1 Settings of the Witness heartbeat resources

To use the Witness heartbeat resources, the following settings are required.

- The communication needs to be available between all the servers using Witness heartbeat resources and the server where the Witness server service operates (Witness server). For the Witness server, refer to "*Witness server service*" in "*7. Information on other settings*".

The Witness heartbeat resources allow to regularly check the server alive information which the Witness server retains. The server alive information is consolidated, which prevents discrepancies with alive information between servers from easily occurring. In addition, by using the HTTP network partition resolution resource as well, "communication disconnection between a local server and Witness server" and "communication disconnection between other servers and Witness server" are distinguished while the Witness heartbeat resources are operated.

### 5.7.2 Notes on the Witness heartbeat resources

- If spaces are included in cluster names, Witness heartbeat resources do not work correctly. Do not use spaces for cluster names.
- In the communication with the Witness server, NIC and a source address are selected according to the OS settings.
- If **Use Proxy** is enabled, **Use SSL** is recommended to be enabled as well. We have confirmed that, when communicating with the Witness server via the proxy server with Squid, the TIME\_WAIT state occurs in a port on the proxy server upon each HTTP request, depending on the behavior of Squid. In the case of HTTPS, however, this phenomenon does not occur.

## **NETWORK PARTITION RESOLUTION RESOURCES DETAILS**

This chapter provides detailed information on network partition resolution resources.

This chapter covers:

- 6.1. *Network partitions*
- 6.2. *Understanding the network partition resolution resources*
- 6.3. *Understanding network partition resolution by PING method*
- 6.4. *Understanding network partition resolution by HTTP method*
- 6.5. *Not resolving network partition*

## **6.1 Network partitions**

Network partitioning status refers to the status where all communication channels have problems and the network between servers is partitioned.

In a cluster system that is not equipped with solutions for network partitioning, a failure on a communication channel cannot be distinguished from an error on a server. This can cause data corruption brought by access from multiple servers to the same resource. EXPRESSCLUSTER, on the other hand, uses resources for network partition resolution to distinguish a failure on a server from network partitioning when a heartbeat from a server is lost. If the lack of heartbeat is determined to be caused by the server's failing, the system performs a failover by activating each resource and rebooting applications on a server running normally. When the lack of heartbeat is determined to be caused by network partitioning, emergency shutdown is executed because protecting data has higher priority over continuity of the operation.

## 6.2 Understanding the network partition resolution resources

Servers in a cluster monitor other servers by using heartbeat resources. When all heartbeat resources are disconnected or other server is shut down by a server not in a cluster, the network partition is solved using network partition resolution resources. The following network partition resolution resource is provided.

Network partition resolution resources	Abbreviation	Function Overview
PING network partition resolution resource (PING method)	pingnp	A network partition is solved by determining a server that can communicate using the ping command.
HTTP network partition resolution resource (HTTP method)	httpnp	A network partition is solved by determining a server that can communicate, sending HTTP HEAD request to Web server.

If there is only one available LAN on the configuration, set the PING network partition resolution resource or the HTTP network partition resolution resource.

## 6.3 Understanding network partition resolution by PING method

### 6.3.1 Settings of the PING network partition resolution resources

To use PING network partition resolution resources, a device that is always active to receive and respond to the ping command (hereafter described as ping device) is required.

When the heartbeat from another server is lost but the ping device is responding to the ping command, the remote server is down. Failover starts.

If there is no response to the ping command, it is determined that the local server is isolated from the network due to network partitioning an action when a network partition occurs is performed.

Fig. 6.1: PING network partition resolution resources (1)

When the heartbeat from the other server is found lost and the ping device does not respond to the ping command, the server is shut down. This prevents a split brain syndrome in the same group of both the active and standby servers.

Fig. 6.2: PING network partition resolution resources (2)

For details, see "*NP Resolution tab*" in "*Cluster properties*" in "*Parameter details*" in this guide.

### 6.3.2 Note on PING network partition resolution resource

When using PING network partition resolution resource, specify addresses which can be sent from and received to through one of the interconnect LANs registered in the configuration information.

In case that response to ping command continues not returning on all the all servers before disconnection of the heartbeat due to ping device failure or other reasons, network partition cannot be resolved. If the heartbeat disconnection is detected in this situation, an action when a network partition occurs is performed on all servers.

It is possible to set **Use** or **Do Not Use** for each server. If **Do Not Use** is set incorrectly, NP resolution processing cannot be performed and a double activation may be detected.

The following is an example of an incorrect setting in which NP resolution processing cannot be performed.

Cluster Properties | cluster

Info Interconnect **NP Resolution** Timeout Port No. Port No.(Mirror) Port No.(Log) Monitor Recovery  
Alert Service WebManager Alert Log Delay Warning Mirror Agent Mirror Driver JVM Monitor Extension

## 6.4 Understanding network partition resolution by HTTP method

### 6.4.1 Settings of the HTTP network partition resolution resources

To use the HTTP network partition resolution resources, the following settings are required.

- An all time running server with HTTP communication available (hereafter referred to as Web server) is needed.

When the heartbeat from another server is detected to be stopped, the HTTP network partition resolution resource operates in the following two ways: If there is a response from Web server, it determines it as a failure of another server and executes the failover. If there is no response from Web server, it determines that the network partition status isolated the local server from the network and executes the same operation as when the network partition occurs.

Fig. 6.3: HTTP network partition resolution resources (1)

When the heartbeat from the other server is found lost and there is no response from the Web server, the server is shut down. This prevents a split brain syndrome in the same group of both the active and standby servers.

Fig. 6.4: HTTP network partition resolution resources (2)

For more information, refer to "*NP Resolution tab*" in "*Cluster properties*" in "*Parameter details*" in this guide.

#### 6.4.2 Note on HTTP network partition resolution resource

In the communication with Web server, NIC and a source address are selected according to the OS settings.

## **6.5 Not resolving network partition**

When this method is selected, network partition resolution is not performed. Therefore, if a failure occurs on all the network channels between servers in a cluster, all servers fail over.

## INFORMATION ON OTHER SETTINGS

This chapter provides the information on the other monitor or notification settings.

This chapter covers:

- *7.1. Shutdown monitoring*
- *7.2. Bonding*
- *7.3. Forced stop*
- *7.4. Script for forced stop*
- *7.5. Chassis Identify*
- *7.6. Alert Service*
- *7.7. SNMP linkage*
- *7.8. Cluster service automatic startup prohibition after improper stop*
- *7.9. Grace period dependence at the automatic failover between server groups*
- *7.10. Witness server service*

## 7.1 Shutdown monitoring

### 7.1.1 Shutdown monitoring

In shutdown monitoring, it is monitored if the OS is stalled when cluster or server shutdown is performed by an EXPRESSCLUSTER command.

If the cluster daemon assumes the OS is stalled, forced reset is executed.

### 7.1.2 Displaying and changing the shutdown monitoring

- **Performs consistently**

Shutdown is monitored. The heartbeat (see "[5. Heartbeat resources details](#)") timeout must be longer than the time required for the OS to shut down, including the applications exiting.

- **Performs only upon the occurrence of a group deactivation failure**

Shutdowns are monitored only upon the occurrence of a group deactivation failure. The heartbeat timeout (see "[5. Heartbeat resources details](#)") must be longer than the time required for the OS to shut down, including that needed for the applications to quit.

It is recommended that you set **Performs only upon the occurrence of a group deactivation failure** if you are using shared disks, mirror disks or hybrid disks.

- **Disable**

Shutdown is not monitored.

### 7.1.3 Shutdown monitoring method

You can select how to monitor shutdown from:

- **Softdog**

For this method, set the timer by using the softdog driver.

- **Ipmi**

For this method, set the timer by using OpenIPMI. If OpenIPMI is not installed, you need to install it. For ipmi, see "[Understanding User mode monitor resources](#)".

- **ipmi(High-End Server Option)**

This cannot be used.

- **Keepalive**

For this method, set the clpkhb and clpka drivers of EXPRESSCLUSTER are used to set the timer.

---

**Note:**

Check the distribution and kernel versions supported by the clpkhb and clpka drivers by referencing Supported distributions and kernel versions" in "Software" in "Installation requirements for EXPRESSCLUSTER" in the "Getting Started Guide".

Check them when applying security patches which are released by a distributor to the operating cluster (when the kernel version is changed).

---

### 7.1.4 Setting of SIGTERM

SIGTERM is issued when shutting down the OS. The range of shutdown stall monitoring and what will be performed at successful OS shutdown are determined by the setting, "Enable SIGTERM handler." When the monitoring method is set to keepalive, what will be performed is the same as when softdog is set.

- Monitoring method: softdog

Successful shutdown (when softdog is selected and SIGTERM is enabled)

- Issue a command (e.g., clpstdn, clpdown, shutdown, reboot).
- Start the shutdown monitoring.
- The shutdown of the OS starts.
- If the OS issues SIGTERM during the shutdown, the shutdown monitoring ends due to enabled SIGTERM.
- The shutdown of the OS succeeds.

Between (d) and (e), no stall can be detected.

Fig. 7.1: Successful shutdown (when softdog is selected for a method of monitoring with enabled SIGTERM)

Successful shutdown (when softdog is selected and SIGTERM is disabled)

- Issue a command (e.g., clpstdn, clpdown, shutdown, reboot).
- Start the shutdown monitoring.
- The shutdown of the OS starts.
- Even if the OS issues SIGTERM during the shutdown, the shutdown monitoring does not end at this point due to disabled SIGTERM.
- The shutdown monitoring ends and the softdog driver is unloaded.  
The shutdown of the OS succeeds.

Fig. 7.2: Successful shutdown (when softdog is selected for a method of monitoring with disabled SIGTERM)

It is recommended to disable SIGTERM if softdog is selected as a method of monitoring.

- Monitoring method: ipmi / ipmi(High-End Server Option)

Successful shutdown (when ipmi is selected and SIGTERM is enabled)

- Issue a command (e.g., clpstdn, clpdown, shutdown, reboot).
- Start the shutdown monitoring.
- The shutdown of the OS starts.
- If the OS issues SIGTERM during the shutdown, the shutdown monitoring ends due to enabled SIGTERM.
- The shutdown of the OS succeeds.

Between (d) and (e), no stall can be detected.

Fig. 7.3: Successful shutdown (when ipmi is selected for a method of monitoring with enabled SIGTERM)

Successful shutdown (when ipmi is selected and SIGTERM is disabled)

- Issue a command (e.g., clpstdn, clpdown, shutdown, reboot).

- (b) Start the shutdown monitoring.
- (c) The shutdown of the OS starts.
- (d) Even if the OS issues SIGTERM during the shutdown, the shutdown monitoring does not end at this point due to disabled SIGTERM.
- (e) The shutdown of the OS succeeds.
- (f) A reset occurs.

Fig. 7.4: Successful shutdown (when ipmi is selected for a method of monitoring with disabled SIGTERM)

- Even if the shutdown is successful without any stalled status, a server is reset by ipmi.
- On a server that can be powered off by software, reset is not performed.

It is recommended to enable SIGTERM if ipmi is selected as a method of monitoring.

- When a stalled status occurs in OS shutdown.

When a stalled status in shutdown is detected

- (a) Issue a command (e.g., clpstdn, clpdown, shutdown, reboot).
- (b) Start the shutdown monitoring.
- (c) The shutdown of the OS starts.
- (d) A stall occurs during the shutdown of the OS.
- (e) A reset occurs.

Fig. 7.5: When a shutdown stall is detected

### 7.1.5 Using heartbeat timeout

Use the timeout value for shutdown monitoring with the heartbeat timeout value.

### 7.1.6 Timeout

Specify the timeout value when the heartbeat timeout value is not used as the timeout value for shutdown monitoring. A value of less than the heartbeat timeout value must be specified to prevent both systems from activating when a failover occurs upon detection of a server down.

## 7.2 Bonding

### 7.2.1 Floating IP resource

#### Notes

If you specify "active-backup" to bonding mode, the communication may be temporarily lost when switching slave interfaces.

#### Bonding setting example

When you configure the settings for FIP resource by the Cluster WebUI, separate the IP address and bonding device with "%" in **Details** tab of **Properties** as described below.

Example: Setting "bond0" as device name, "192.168.1.3" as IP address

The screenshot shows a web interface window titled "Resource Properties | fip1". It has a dark header bar with the title and a close button. Below the header, there are four tabs: "Info", "Dependency", "Recovery Operation", and "Details". The "Details" tab is selected. Under the "Details" tab, there are two sub-tabs: "Common" and "server1 server2". The "Common" sub-tab is active. In the "Common" sub-tab, there is a field labeled "IP Address\*" with the value "192.168.1.3%bond0". Below this field is a "Tuning" button. At the bottom right of the window are three buttons: "OK", "Cancel", and "Apply".

**Note:** For interconnection IP address, specify IP addresses only.

The following shows example settings to use FIP resource on bonding:

Device	Slave	Mode
bond0	eth0 eth1	active-backup(1) balance-tlb(5)
bond0	eth0 eth1	active-backup(1) balance-tlb(5)

For Server 1 and Server 2 in the figure below, slave interfaces eth0 and eth1 are combined by bonding to constitute a master interface bond0. To access Server 1 and Server 2, an IP address is set for the floating IP resource. It is possible for both the host on the same LAN as the cluster server and the host on the remote LAN to connect to the cluster server with the floating IP. The router does not need specific settings for using the floating IP.

- IP address for the floating IP resource: 192.168.1.3%bond0

Fig. 7.6: An example of the floating IP resource on bonding

When FIP resource is enabled on srv1 by ifconfig: (bonding mode is set to "balance-tlb(5).")

```
$ ifconfig
bond0    Link encap:Ethernet HWaddr 00:00:01:02:03:04
         inet addr:192.168.1.1 Bcast:192.168.1.255 Mask:255.255.255.0
         UP BROADCAST RUNNING MASTER MULTICAST MTU:1500 Metric:1
         RX packets:6807 errors:0 dropped:0 overruns:0 frame:0

         TX packets:1494 errors:0 dropped:0 overruns:0 carrier:0
         collisions:0 txqueuelen:1000
         RX bytes:332303 (324.5 Kb)  TX bytes:94113 (91.9 Kb)
```

(continues on next page)

(continued from previous page)

```

Interrupt:18 Base address:0x2800 Memory:fc041000-fc041038

eth1  Link encap:Ethernet HWaddr 00:00:05:06:07:08
      UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
      RX packets:215 errors:0 dropped:0 overruns:0 frame:0
      TX packets:1627 errors:0 dropped:0 overruns:0 carrier:0
      collisions:0 txqueuelen:1000
      RX bytes:77162 (75.3 Kb)  TX bytes:141394 (138.0 Kb)
      Interrupt:19 Base address:0x2840 Memory:fc042000-fc042038

eth2  Link encap:Ethernet HWaddr 00:00:09:10:11:12
      inet addr:192.168.2.1 Bcast:192.168.2.255 Mask: 255.255.255.0
      UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
      RX packets:47 errors:0 dropped:0 overruns:0 frame:0
      TX packets:1525 errors:0 dropped:0 overruns:0 carrier:0
      collisions:0 txqueuelen:1000
      RX bytes:2820 (2.7 Kb)  TX bytes:110113 (107.5 Kb)
      Interrupt:24 Base address:0x3000 Memory:fc500000-fc500038

```

- The above block of "bond0" to be used for the public LAN or the second interconnect indicates the data on a device with eth0 and eth1 combined for bonding.
- The block of "bond0:0" shows the data on the floating IP address activated on bond0.
- "eth2" is a device to be used for the first interconnect.

## 7.2.2 Mirror disk connect

### Notes

It is not recommended to use a mirror disk connect on bonding because communication may be interrupted temporarily when switching slave interfaces. Depending on the timing of mirroring, mirror recovery may be performed after switching bonding has completed.

### An example of bonding setup

The following is an example of setting up bonding on a mirror disk connect:

Cluster Server	Device	Slave	Mode
srv1	bond0	eth1 eth2	balance-rr(0) active-backup(1) balance-tlb(5)
srv2	bond0	eth1 eth2	balance-rr(0) active-backup(1) balance-tlb(5)

## 7.3 Forced stop

### 7.3.1 What is Forced stop?

This function forcibly stops the failing server by the another normal server when it is recognized that the server is failing.

This function stops a physical machine by using the IPMI function.

It stops the guest OS on a virtual machine by using the VMware vCenter Server function.

In addition to the functions above, you can execute a script in which the procedure for stopping the failing server is written. For details, refer to "*Script for forced stop*" in "*7. Information on other settings*" in this guide.

### 7.3.2 Conditions for performing forced stop

- Forced stop is not performed in the following cases:
  - When the failover group successfully stops before the server fails
  - When the server is shut down by the clpdown command, the OS shutdown command or Cluster WebUI and the failover group successfully stops
  - When the cluster is stopped by the clpcl command or Cluster WebUI and the failover group successfully stops
  - When the server fails and there is no failover group to perform failover from the failing server to another server  
(including when the failover group is not activated in the failing server)
- Forced stop is performed in the following case:
  - When the server is failing and there is a failover group to perform failover from the failing server to another server

### 7.3.3 Commands to be used for forced stop

The ipmitool command is used.

Configure the following option values for the command execution on the **BMC** tab of the server properties.

Options for the ipmitool command	Information configured on the BMC tab of the server properties
-H <i>ip_address</i>	IP address
-U <i>username</i>	User name
-P <i>password</i>	Password

When a command line is not specified for **Forced Stop Action** in the BMC tab of the server properties, the following commands are executed.

Forced Stop Action	Parameters
BMC Power Off	ipmitool -H <i>ip_address</i> -U <i>username</i> -P <i>password</i> power off
BMC Reset	ipmitool -H <i>ip_address</i> -U <i>username</i> -P <i>password</i> power reset
BMC Power Cycle	ipmitool -H <i>ip_address</i> -U <i>username</i> -P <i>password</i> power cycle

Continued on next page

Table 7.4 – continued from previous page

Forced Stop Action	Parameters
BMC NMI	ipmitool -H <i>ip_address</i> -U <i>username</i> -P <i>password</i> power diag

If the above commands fail, execute the following commands:

Forced Stop Action	Parameters
BMC Power Off	ipmitool -H <i>ip_address</i> -I <i>lanplus</i> -U <i>username</i> -P <i>password</i> power off
BMC Reset	ipmitool -H <i>ip_address</i> -I <i>lanplus</i> -U <i>username</i> -P <i>password</i> power reset
BMC Power Cycle	ipmitool -H <i>ip_address</i> -I <i>lanplus</i> -U <i>username</i> -P <i>password</i> power cycle
BMC NMI	ipmitool -H <i>ip_address</i> -I <i>lanplus</i> -U <i>username</i> -P <i>password</i> power diag

See "*IPMI command*" in "4. Monitor resource details" of "*Monitor resource*" for the options used for the actions.

The vmcontrol command of the VMware vSphere Command Line Interface (vCLI) is used to forcibly stop the guest OS on a virtual machine. This function cannot be used if VMware vSphere Command Line Interface (vCLI) is not installed.

Specify the following option values for the command execution.

Option for the vmcontrol command	Information configured for Virtual Machine Forced Stop Setting on the Extension tab of the cluster properties	Information configured for Input for Virtual Machine name on the Info tab of the server properties
--server <i>ip_address</i>	IP address	-
--username <i>username</i>	user name	-
--password <i>password</i>	password	-
--vmname <i>virtualmachine</i>	-	Virtual machine name

The following option is used for action.

Command	Option	Description
vmcontrol	--operation poweroff	Powers off the guest OS on a virtual machine

### 7.3.4 Specifying the command to be used for forced stop

It is also possible to forcibly stop a physical machine server by specifying an arbitrary command line to be used for the forced stop in **Forced Stop Action** in the BMC tab of the server properties.

To specify the command line, use the following replacement strings so that the setting values of the server properties are applied on the command line.

Replacement string name	Replacement target (Setting item in the BMC tab of the server properties)	Replacement target (Setting item in the forced stop action in the extension tab of the cluster properties)
CLP_BMC_HOST	IP address	-
CLP_BMC_USER	User name	-

Continued on next page

Table 7.8 – continued from previous page

Replacement string name	Replacement target (Setting item in the BMC tab of the server properties)	Replacement target (Setting item in the forced stop action in the extension tab of the cluster properties)
CLP_BMC_PASSWORD	Password	-
CLP_BMC_ACTION	-	Forced Stop Action

Characters to be replaced by the replacement string (CLP\_BMC\_ACTION) for the forced stop action are as follows.

Forced Stop Action	Characters to be replaced by replacement string
BMC Power Off	off
BMC Reset	reset
BMC Power Cycle	cycle
BMC NMI	diag

**Note:** In the forced stop action, the action to be executed differs depending on whether the replacement string, CLP\_BMC\_ACTION is specified or not.

- When CLP\_BMC\_ACTION is included in the command line:  
The action selected in the forced stop action of the cluster properties is executed.
- When CLP\_BMC\_ACTION is not included in the command line:  
The action selected in the forced stop action of the cluster properties is not applied.

Example of the command specified for the forced stop action by using the replacement strings:

```
ipmitool -H CLP_BMC_HOST -U CLP_BMC_USER -P CLP_BMC_PASSWORD power  
CLP_BMC_ACTION
```

### 7.3.5 Displaying and changing the details of forced stop

For the forced stop settings, refer to "*Cluster properties - Extension tab*", "*Server properties - Info tab*", and "*Server properties - BMC tab*" in "2. Parameter details" in this guide.

### 7.3.6 Notes on the forced stop

- Forcibly stopping the guest OS on a virtual machine  
Only power off operation can be performed. This function cannot be used if communication with VMWare vCenter Server cannot be performed.
- Notes on ipmitool  
See "*IPMI command*" in "4. Monitor resource details" of "*Monitor resource*".
- Impacts of forced stop  
When you use the forced stop function, the following functions are influenced because power off, reset, power cycle or NMI is forcibly performed regardless of the OS or server status.
  - Dump collection

Since it is not recognized that dump files are being collected, power off, reset or power cycle is performed even though dump collection is being performed, so dump collection does not complete.

- Power on within the heartbeat timeout

When the server is powered on again for the purpose of maintenance etc. within heartbeat timeout, power off, reset, power cycle or NMI may occur after heartbeat timeout has elapsed.

- BMC network settings

Configure the settings so that the IP address of the LAN port for BMC management and the IP address which OS uses can communicate with each other. This function cannot be used in the environment where the network for the BMC management is blocked.

Set the same IP address that is configured in the LAN port for the BMC management to the **BMC** tab of the server properties.

See the server's manuals etc. for information on how to configure the IP address of the LAN port for the BMC management etc.

## 7.4 Script for forced stop

### 7.4.1 What is the script for forced stop?

When it is recognized that the server is failing, any script created by the user can be executed on one of the rest of servers working normally.

The failing server can be stopped forcibly by using the script.

Moreover, using the script enables to check whether the forced stop is successful or unsuccessful and to control whether to execute the failover or not.

### 7.4.2 Conditions for executing the script for forced stop

- The script for forced stop is not executed when:
  - The failover group successfully stops before the server fails
  - The server is shut down by the clpdown command, the OS shutdown command or Cluster WebUI and the failover group successfully stops
  - The cluster is stopped by the clpcl command or Cluster WebUI and the failover group successfully stops
  - The server fails and there is no failover group to perform failover from the failing server to another server (including when the failover group is not activated in the failing server)
- The script for forced stop is executed when the server is failing and there is a failover group to perform failover from the failing server to another server.

### 7.4.3 Features of the script for forced stop

#### Environment variables used in the script for forced stop

EXPRESSCLUSTER stores the data such as the information of a failing server to environment variables.

You can use the following environment variables for branch conditions in the script to describe the procedure tailored to the operations of your system.

Environment variable	Setting value	Description
CLP_SERVER_DOWN ...Down server name	Server name	Specifies the name of the failing server
CLP_SERVER_LOCAL ...Local server name	Server name	Specifies the name of the server where the script is executed.
CLP_VMNAME ...Virtual machine name	Virtual machine name	Specifies the virtual machine name set in the server properties.

Continued on next page

Table 7.10 – continued from previous page

Environment variable	Setting value	Description
CLP_DATACENTER_NAME ...Data center name	Data center name	Specifies the data center name set in the server properties.
CLP_VCENTER_HOST ...Host name for vCenter	Host name	Specifies the host name set in the virtual machine forced stop setting.
CLP_VCENTER_USER ...User name for vCenter	User name	Specifies the user name set in the virtual machine forced stop setting.
CLP_VCENTER_PASSWORD ...Password for vCenter	Password	Specifies the password set in the virtual machine forced stop setting.
CLP_BMC_HOST ...IP address for BMC	IP Address	Specifies the IP address set in the server properties.
CLP_BMC_USER ...User name for BMC	User name	Specifies the user name set in the server properties.
CLP_BMC_PASSWORD ...Password for BMC	Password	Specifies the password set in the server properties.

**Return value of the script for forced stop**

Return 0 when the script terminates normally.

**7.4.4 Displaying and changing the details of the script for forced stop**

For the settings of the script for forced stop, refer to "*Extension tab*" in "*Cluster properties*" in "*2. Parameter details*" in this guide.

**7.4.5 Notes on the script for forced stop**

- Describe the customer-defined process in the script to stop the server.
- When using the script for forced stop, refer to "*Notes on the forced stop* - Impacts on forced stop" of "*Forced stop*" in "*7. Information on other settings*" in this guide.
- When the forced stop function and the script for forced stop is used together, they are executed in the following order.
  1. The forced stop function
  2. The script for forced stop

## 7.5 Chassis Identify

### 7.5.1 Chassis identify

This function allows for the other normal server to report the server failure by blinking the chassis ID lamp of a failing server by using the IPMI function when it recognizes that the server is failing

### 7.5.2 Conditions for chassis ID lamp to blink

- The chassis ID lamp does not blink in the following cases:
  - When the status other than server status becomes abnormal
  - When cluster shutdown is performed
  - When all the servers in the cluster fail  
When the servers do not go down simultaneously, they blink for 250 seconds at the maximum, and eventually the chassis ID lamps of all servers go off.
  - When BMC of the failing server cannot communicate with the normal server
  - When there are normal servers in the cluster but EXPRESSCLUSTER is stopped
- The chassis ID lamp blinks in the following cases (the above conditions for not blinking are given priority over these conditions when they overlap):
  - When some of the servers in the cluster fail due to some abnormality
  - When some of the servers in the cluster are shut down by the shutdown command of the OS.
  - When some of the servers in the cluster are shut down by the clpdown command or Cluster WebUI
  - When EXPRESSCLUSTER is stopped by the clpcl command or Cluster WebUI in some of the servers in the cluster
  - When cluster service automatic startup is off in some of the servers in the cluster
- Chassis ID lamp stops blinking and goes off in the following cases:
  - When there are normal servers in the cluster, and the server status of the failing server returns to normal

### 7.5.3 Behavior of the chassis ID lamp blinking when the cluster stops

If the chassis ID lamp of a server in the cluster is in the blinking status when the cluster stops, the chassis ID lamp may keep blinking for 250 seconds at the maximum.

### 7.5.4 Commands to be used for chassis identify

The ipmitool command is used.

If the commands are not installed, this function cannot be used.

Specify the following option values for the command execution in the **BMC** tab of **Server Properties**.

The <code>alarms/ialarms</code> command option	Configured in the BMC tab of the server properties
<code>-N ip_address</code>	IP address
<code>-U username</code>	Use name
<code>-P password</code>	Password

When the command lines are not specified for **Flash** and **Turn off** of the chassis identify lamp in the **BMC** tab of the server properties, the following command is executed.

In case of alarms:

Chassis Identify	Parameters
Flash	<code>ipmitool -H ip_address -U username -P password chassis identify 250</code>
Turn off	<code>ipmitool -H ip_address -U username -P password chassis identify 0</code>

In case of ialarms:

Chassis Identify	Parameters
Flash	<code>ipmitool -H ip_address -I lanplus -U username -P password chassis identify 250</code>
Turn off	<code>ipmitool -H ip_address -I lanplus -U username -P password chassis identify 0</code>

## 7.5.5 Specifying the command to be used for the chassis identify function

It is also possible to execute the chassis identify function by specifying an arbitrary command line used for the chassis identify function in **Flash** and **Turn off** of the chassis identify lamp in the **BMC** tab of the server properties.

To specify the command line, use the following replacement strings so that the setting values of the server properties are applied to the command line.

replacement strings name	Replacement target (Setting item in the BMC tab of the server properties)
<code>CLP_BMC_HOST</code>	IP address
<code>CLP_BMC_USER</code>	Use name
<code>CLP_BMC_PASSWORD</code>	Password

Example of the chassis identify command specified by using the replacement strings:

```
ipmitool -H CLP_BMC_HOST -U CLP_BMC_USER -P CLP_BMC_PASSWORD chassis identify 250
```

## 7.5.6 Displaying and changing the chassis identify details

For the chassis identify settings, refer to "*Cluster properties - Alert Service tab*" and "*Server properties - BMC tab*" in "*2. Parameter details*" in this guide.

## 7.5.7 Notes on Chassis identify

- Notes on ipmitool  
See "*IPMI command*" in "*Monitor resource*" in "*4. Monitor resource details*".
- BMC network settings  
Configure the settings so that the IP address of the LAN port for BMC management and the IP address which OS uses can communicate with each other. This function cannot be used in the environment where the network for the BMC management is blocked.  
Set the same IP address that is configured in the LAN port for the BMC management to the **BMC** tab of the server properties.  
See the server's manuals etc. for information on how to configure the IP address of the LAN port for the BMC management etc.

## 7.6 Alert Service

### 7.6.1 What is Alert Service?

EXPRESSCLUSTER X Alert Service (hereafter Alert Service) is a function to report failures mentioned above found in EXPRESSCLUSTER-installed cluster systems to system administrators in remote locations.

Failures are reported in three ways, each serving a different purpose.

1. E-mail report  
Alert messages in the Cluster WebUI are sent by e-mail to administrators.
2. Network Warning light  
The network warning light is a visual display of the status of the server. When the server shuts down successfully, the network warning light goes off.  
The e-mail report and the network warning light function work independently of each other.
3. SNMP trap sending  
When a Cluster WebUI alert message is displayed, the contents of the alert are sent with an SNMP trap.

Fig. 7.7: Alert service

Alert Service allows you to:

- Receive information about failures while not physically located in the same place as the management PC. This is achieved via e-mail reporting function.
- Receive e-mail messages on your mobile phone.
- Visually be alerted of failures by viewing the network warning light.
- Recognize a failure audibly by reproducing the audio file for the network warning light.
- Notify the servers that are configured as the destination of the details of errors by SNMP trap sending.

Mail Report notifies the content of the alert in the following format by e-mail.

Subject:

EXPRESSCLUSTER

Body:

```
Message: Server [down server] has been stopped.  
Type: nm  
ID: 2  
Host: [mail sending source server name]  
Date: [send time stamp]
```

## 7.6.2 Notes on Alert Service

- To use the mail report and network warning light functions, EXPRESSCLUSTER X Alert Service 4.3 for Linux is required.
- The task of Alert Service is to send the first report of failure but not to examine or find the cause of failure. When a failure occurs, instead of using the Alert Service, try other methods, such as viewing EXPRESSCLUSTER logs or syslog, to find out the cause of the error.
- If you use the Linux network warning light function, it may prove necessary to install the rsh package

## 7.6.3 Mail report actions

- Alert Service sends the same messages as the Cluster WebUI. See "*Messages reported by syslog, alert, mail, SNMP trap, and Message Topic*" in "*10. Error messages*" in this guide for information on which alert messages to be sent.
- You can change the alerts that are reported by e-mail. For more information, see "*Cluster properties - Alert Service tab*" in "*2. Parameter details*" in this guide.

## 7.6.4 Network Warning Light status

The network warning light performs the following operations.

1. When the server is started  
When the server starts up successfully, warning light changes to green.
2. When the server shuts down  
When the server shuts down successfully, warning light goes off.
3. When the server fails  
When the server fails, its warning light flashes in red. If all servers in the cluster fail, the warning light of the server that failed last will not work because the network warning light is controlled by a normal server that monitors other servers.

Once the network warning light is lit or starts flashing, it will not go off until the cluster shuts down. Run the clplamp command introduced in the following section to put the light out. For more information on the clplamp command, see "*Turning off warning light (clplamp command)*" in "*8.2. EXPRESSCLUSTER commands*" in this guide.

For a network warning light (specified by NEC) that supports playback of an audio file, the setting also enables audio file reproduction to link to On/Off.

### 7.6.5 Operations of SNMP trap sending

- The contents of Cluster WebUI alert messages are sent with an SNMP trap. For alert messages subject to SNMP trap sending, see "*Messages reported by syslog, alert, mail, SNMP trap, and Message Topic*" in "*10. Error messages*" in this guide.
- The alerts subject to SNMP trap sending can be changed. For more information, see "*Cluster properties - Alert Service tab*" in "*2. Parameter details*" in this guide.
- For details on the SNMP trap, see "*SNMP trap sending*".

## 7.7 SNMP linkage

### 7.7.1 SNMP linkage

SNMP linkage enables SNMP trap sending from EXPRESSCLUSTER and information acquisition by SNMP from an SNMP manager according to the EXPRESSCLUSTER MIB definitions.

Fig. 7.8: SNMP linkage

### 7.7.2 EXPRESSCLUSTER MIB definitions

The information sent/acquired with SNMP linkage is configured by the MIB definition files.

To use the functions of SNMP trap sending and information acquisition by SNMP, described later, MIB definition files are required.

To receive SNMP traps from EXPRESSCLUSTER by using an SNMP manager, or to acquire cluster statuses from an SNMP manager, set the EXPRESSCLUSTER MIB definition files in the SNMP manager.

For how to set the MIB definition files in an SNMP manager, refer to the manual for the SNMP manager.

The EXPRESSCLUSTER MIB definition files are placed in the following directory on the EXPRESSCLUSTER X CD-ROM.

<EXPRESSCLUSTER\_X\_CD-ROM>\Common\<version number>\common\mib

The MIB definition files provide the functions described below.

No.	MIB definition file	Description
1.	NEC-CLUSTER-SMI.mib	Configures the EXPRESSCLUSTER MIB tree root path.
2.	NEC-CLUSTER-EVENT-MIB.mib	Configures the trap and MIB definitions for the EXPRESSCLUSTER SNMP trap sending function.
3.	NEC-CLUSTER-MANAGEMENT-MIB.mib	Configures MIB definitions for the following EXPRESSCLUSTER information: - Cluster information - Server information - Group information

The available functions depend on the files set in the SNMP manager.

**To receive SNMP traps from EXPRESSCLUSTER:**

1. NEC-CLUSTER-SMI.mib
2. NEC-CLUSTER-EVENT-MIB.mib

**To acquire information by SNMP:**

1. NEC-CLUSTER-SMI.mib
3. NEC-CLUSTER-MANAGEMENT-MIB.mib

### 7.7.3 SNMP trap sending

SNMP trap sending serves to send the contents of Cluster WebUI alert messages to the SNMP manager.

To send a trap, the SNMP trap sending destination is required to be configured. Configure it by referring to Destination Settings of SNMP Trap in "*Alert Service tab*" in "*Cluster properties*" in "*2. Parameter details*" in this guide.

The traps to be sent are defined by NEC-CLUSTER-EVENT-MIB.

NEC-CLUSTER-EVENT-MIB defines the following MIB objects.

**clusterEventNotifications group**

This group defines the traps to be sent. The MIB objects defined for the group function as described below.

No.	SNMP TRAP OID	Description
1.	clusterEventInformation	Trap for information level alerts. A clusterEvent group MIB object is attached.
2.	clusterEventWarning	Trap for warning level alerts. A clusterEvent group MIB object is attached.
3.	clusterEventError	Trap for error level alerts. A clusterEvent group MIB object is attached.

### **clusterEvent group**

This group defines the information appended to the traps. The MIB objects defined for the group function as described below.

No.	SNMP OID	Description
1.	clusterEventMessage	Indicates the alert message.
2.	clusterEventID	Indicates the event ID.
3.	clusterEventDateTime	Indicates the time at which the alert originated.
4.	clusterEventServerName	Indicates the server from which the alert originated.
5.	clusterEventModuleName	Indicates the module from which the alert originated.

## **7.7.4 Information acquisition by SNMP**

By using the SNMP protocol, some information about the EXPRESSCLUSTER configuration and status can be acquired. However, EXPRESSCLUSTER does not include SNMP agent functions. For an SNMP agent, the Net-SNMP snmpd daemon needs to be implemented separately.

### **SNMP agent**

The SNMP agent serves to return a response about the configuration information or status information (GetResponse) to information acquisition requests (GetRequest, GetNextRequest) from an SNMP manager (network management software).

---

**Note:** To use information acquisition by SNMP, you must take the steps described in "Setting up the SNMP linkage function" in the "Installation and Configuration Guide".

---

## **7.7.5 MIB objects acquirable with SNMP linkage**

The MIB objects that can be acquired with the SNMP linkage function are defined by NEC-CLUSTER-MANAGEMENT-MIB.

NEC-CLUSTER-MANAGEMENT-MIB defines the following MIB objects.

### **clusterGeneral group**

This group is used to acquire cluster information. The MIB objects defined for the group function as described below.

No.	SNMP OID	Description
1.	clusterName	Indicates the name of the cluster.
2.	clusterComment	Indicates the comment of the cluster.
3.	clusterStatus	<p>Indicates the current status of the cluster. The correspondence between the MIB value and the Cluster WebUI status is as described below.</p> <pre> MIB value  status ----- normal     Normal caution   Caution error      Error unknown    - </pre>

### clusterServer group

This group is used to acquire server information. Indexes on acquisition of clusterServerTable are sorted by server priority. The MIB objects defined for the group function as described below.

No.	SNMP OID	Description
1.	clusterServerLocalServerIndex	Indicates the index of the server receiving the present SNMP information acquisition request (clusterServerIndex).
2.	clusterServerTable	Indicates the information table for the server.
3.	clusterServerEntry	Indicates the server information list. The index for the list is clusterServerIndex.
4.	clusterServerIndex	Indicates the index for uniquely identifying the server.
5.	clusterServerName	Indicates the name of the server.
6.	clusterServerComment	Indicates a comment for the server.
7.	clusterServerStatus	<p>Indicates the current status of the server. The correspondence between the MIB value and the Cluster WebUI status is as described below.</p> <pre> MIB value      Group type ----- failover       Failover group cluster        Management group virtualMachine Virtual machine →group </pre> <p>Values other than those indicated above may be acquired depending on the status of the server.</p>

Continued on next page

Table 7.19 – continued from previous page

No.	SNMP OID	Description
8.	clusterServerPriority	Indicates the priority of the server.
9.	clusterServerProductName	Indicates the name of the EXPRESSCLUSTER product installed on the server.
10.	clusterServerProductVersion	Indicates the version of the EXPRESSCLUSTER product installed on the server.
11.	clusterServerProductInstallPath	Indicates the installation path of EXPRESSCLUSTER on the server.
12.	clusterServerPlatformName	Indicates the name of the platform on the server.

### **clusterGroup group**

This group is used to acquire group information. The MIB objects defined for the group function as described below.

No.	SNMP OID	Description
1.	clusterGroupTable	Indicates the information table for the group.
2.	clusterGroupEntry	Indicates the group information list. The index for the list is clusterGroupIndex.
3.	clusterGroupIndex	Indicates the index for uniquely identifying the group.
4.	clusterGroupName	Indicates the name of the group.
5.	clusterGroupComment	Indicates a comment for the group.
6.	clusterGroupType	Indicates the type of the group. The correspondence between the MIB value and the group type is as described below.  <div style="display: flex; justify-content: space-between;"> <div>MIB value</div> <div>Group type</div> </div> <div style="border-top: 1px dashed black; margin-top: 5px;"> <div style="display: flex; justify-content: space-between;"> <div>failover</div> <div>Failover group</div> </div> <div style="display: flex; justify-content: space-between;"> <div>cluster</div> <div>Management group</div> </div> <div style="display: flex; justify-content: space-between;"> <div>virtualMachine</div> <div>Virtual machine group</div> </div> </div>

Continued on next page

Table 7.20 – continued from previous page

No.	SNMP OID	Description																
7.	clusterGroupStatus	<p>Indicates the current status of the group. The correspondence between the MIB value and the Cluster WebUI status is as described below.</p> <table><tr><th>MIB value</th><th>status</th></tr><tr><td>online</td><td>Online</td></tr><tr><td>onlineFailure</td><td>Online Failure</td></tr><tr><td>offlineFailure</td><td>Offline Failure</td></tr><tr><td>offline</td><td>Offline</td></tr><tr><td>unknown</td><td>Unknown</td></tr><tr><td>onlinePending</td><td>Online Pending</td></tr><tr><td>offlinePending</td><td>Offline Pending</td></tr></table>	MIB value	status	online	Online	onlineFailure	Online Failure	offlineFailure	Offline Failure	offline	Offline	unknown	Unknown	onlinePending	Online Pending	offlinePending	Offline Pending
MIB value	status																	
online	Online																	
onlineFailure	Online Failure																	
offlineFailure	Offline Failure																	
offline	Offline																	
unknown	Unknown																	
onlinePending	Online Pending																	
offlinePending	Offline Pending																	
8.	clusterGroupCurrentServerIndex	<p>Indicates the index of the server on which the group is currently active (clusterServerIndex). The return value of a deactivated group is -1.</p>																

## 7.8 Cluster service automatic startup prohibition after improper stop

### 7.8.1 Cluster service automatic startup prohibition

This function prohibits the EXPRESSCLUSTER service from automatically starting up at the next OS activation after the cluster has been shut down, reboot, or stopped by Cluster WebUI or the EXPRESSCLUSTER service has been stopped by using a command other than the `clpstdn` command and the `clpcl -t -a` command.

When the automatic startup prohibition setting is enabled, the EXPRESSCLUSTER service will not automatically start at the next server activation after the cluster has been shut down, reboot, or stopped by Cluster WebUI or the EXPRESSCLUSTER service has been stopped by using a command other than the `clpstdn` command and the `clpcl -t -a` command.

Even in cases where cluster shutdown or cluster stop is executed, if an error occurs in the EXPRESSCLUSTER service stop sequence, or if the stop sequence is not executed due to the likes of an OS reset or a power interruption, the EXPRESSCLUSTER service will not automatically start at the next OS activation.

### 7.8.2 Displaying and changing the automatic startup prohibition setting

- **Cluster service's not stop normal, prohibit automatic startup**  
Prohibits cluster service automatic startup at the next OS activation if the servers are stopped by a means other than cluster shutdown or cluster stop, or if the cluster shutdown or stop sequence does not finish successfully.
- **Not prohibit cluster service automatic startup after improper stop**  
Does not prohibit cluster service automatic startup.

### 7.8.3 Conditions for automatic startup prohibition

The conditions for automatic startup prohibition are as described below.

- The cluster is stopped by a means other than cluster shutdown or cluster stop.
- The cluster service stop sequence is not executed due to a reason such as an OS reset, panic, or power interruption.
- Group deactivation fails in the cluster service stop sequence as a result of cluster shutdown or stop.
- The cluster is stopped on one of the servers comprising the cluster.

### 7.8.4 Notes on automatic startup prohibition

- At OS activation, if the EXPRESSCLUSTER service does not start automatically, activate the EXPRESSCLUSTER service by using Cluster WebUI or the `clpcl` command.
- At OS activation, if the EXPRESSCLUSTER service does not start automatically, Cluster WebUI alert messages and syslog messages are output.

## 7.9 Grace period dependence at the automatic failover between server groups

### 7.9.1 What is the grace period dependence?

One server group waits specified time for the other server group to start failover when the automatic failover is executed between server groups. When the grace period elapsed after the server down was detected, the failover is executed.

### 7.9.2 Condition for the grace period dependence

One server group waits for the other server group with any of the following configurations to start the failover.

- **Use Server Group settings** in the **Info** tab is selected.
- Multiple server groups are specified for **Server Groups that can run the Group** in the **Startup Server** tab.
- **Prioritize server group failover policy** is selected and **Enable only manual failover among the server group** is not selected for **Auto Failover** of **Failover Attribute** in the **Attribute** tab.

In the following cases, one server group does not wait specified time for the other server group to start failover:

- One server executes the failover to another server within the same server group.
- The server down is detected by the server down notification.
- The script for forced stop is successfully executed while **Execute Script for Forced Stop** is selected, or the condition not to execute the script for forced stop is met.
- The forced stop is successfully executed while **Execute Script for Forced Stop** is not selected and **Use Forced Stop** is selected, or the condition not to execute the forced stop is met.
- The NP resolution resource is configured.

### 7.9.3 Displaying and changing the grace period dependence

Specify the waiting time for **Grace period of server group failover policy**.

If 0 is specified, one server group does not wait for the other server group to start failover.

### 7.9.4 Notes on the grace period dependence

If any operation is done for the failover target group while the other server group waits during the grace period, the settings to wait during the grace period is canceled and the other server group does not failover.

If the once-failed server is detected to be alive while the other server waits during the grace period, the settings to wait during the grace period is canceled and the failover is not executed.

If the failover target server goes down, the failover may start later than when the grace period ends.

## 7.10 Witness server service

### 7.10.1 What is Witness server service?

Witness service is the service to receive Witness heartbeat from each server in the cluster and send back the status information of receiving the heartbeat from each server as a response. It is installed in a server outside of the cluster.

Fig. 7.9: Witness server service

### 7.10.2 Notes on Witness server service

- Witness server service operates in Node.js environment. Therefore, Node.js needs to be installed before the installation of the Witness server service.

### 7.10.3 Operation verified environment for Witness server service

Its operation has been verified in the following environments.

OS	Requirement	Version
Windows Server 2012 R2	Node.js 10.13.0	4.1.0
Windows Server 2019	Node.js 12.10.0	4.2.0
Red Hat Enterprise Linux 7.4	Node.js 8.12.0	4.1.0
Red Hat Enterprise Linux 8.0	Node.js 12.10.0	4.2.0

### 7.10.4 How to install Witness server service

Install the Witness server service by using npm command for Node.js environment. Store the Witness server service module in an arbitrary folder, and execute the following command.

```
> npm install --global clpwitnessd-<version>.tgz
```

### 7.10.5 How to configure Witness server service

To change the settings of Witness server service, edit the configuration file directly. Open the folder indicated in the first row of the execution results of the command below.

```
> npm list --global clpwitnessd
```

Example of execution results:

```
C:\Users\Administrator\AppData\Roaming\npm  
`-- clpwitnessd@4.1.0
```

Edit clpwitnessd.conf.js that is stored in node\_modules\clpwitnessd under the opened folder, with a text editor such as notepad.

Setting items are as follows.

Item	Default	Description
http.enable	True	Specify whether to execute HTTP server or not. true: execute false: not execute
http.port	80	Specify the wait port number for HTTP server.
http.keepalive	10000	Specify the keep alive time for HTTP server in milliseconds.
https.enable	False	Specify whether to execute HTTPS server or not. true: execute false: not execute
https.port	443	Specify the wait port number for HTTPS server.
https.keepalive	10000	Specify the keep alive time for HTTPS server in milliseconds.
https.ssl.key	server_key.pem	Specify a secret key file to be used for HTTPS server.
https.ssl.crt	server_cert.pem	Specify a certification file to be used for HTTPS server.
log.directory	-	Specify the log output destination folder.
log.level	info	Specify the log output level. error: Only error logs are output. warn: Error logs and warning logs are output. info: Warning logs and information logs are output. debug: Information logs and detailed logs are output.
log.size	1024 * 1024 * 512	Specify the log rotation size in bytes.
data.available	10000	Specify the default time limit for the communication status information of the cluster server in milliseconds.

### 7.10.6 How to execute Witness server service

Execute the following command to start up Witness server service in the foreground. For how to execute the Witness server service as Windows service or Linux daemon, refer to the following section, "[Using Witness server service as the OS service](#)".

> clpwitnessd

### 7.10.7 Using Witness server service as the OS service

If you want to start Witness server service at the OS startup, the Witness server service requires to be registered as the OS service.

The following exemplifies how to register Witness server service as the OS service (in case of Windows service control manager and Linux systemd). The method of registration for the OS service differs depending on the environment. Configure the registration to suit your environment by referring to the explanation below.

#### Registration for Windows service control manger

The following exemplifies the procedure to register by using npm package winser.

1. Install winser by npm command. Use the following command so that winser package is downloaded from npm repository and then installed.  
  
> **npm install --global winser**
2. Create a folder to execute the service in any location. By default, this folder stores log files, SSL secret key file and SSL certificate file.
3. Create package.json file for the service registration with winser, under the folder created in the above step 2. Enter "\" to separate the characters of the path. The path specified for "start" is line-fed for the convenience of character numbers but actually is in one row.

```
{
  "name": "clpwitnessd-service",
  "version": "1.0.0",
  "license": "UNLICENSED",
  "private": true,
  "scripts": {
    "start": "C:\\Users\\Administrator\\AppData\\Roaming\\npm\\clpwitnessd.cmd
↵"
  }
}
```

4. Execute winser command to register and start the Witness server service.  
  
> **winservice -i -a**
5. Select **Control Panel -> Administration Tools -> Service**, and confirm that the service (ex. clpwitnessd-service) with the name specified for "name" of package.json has been registered.

#### Registration for Linux systemd

The following exemplifies the procedure to register by creating the unit file of systemd.

1. Create a directory to execute the service in any location. By default, this folder stores log files, SSL secret key file and SSL certificate file.  
(ex. /opt/clpwitnessd) (ex. /opt/clpwitnessd)
2. Create the unit file of the Witness server service in /etc/systemd/system.  
(ex. clpwitnessd.service) (ex. clpwitnessd.service)

```
[Unit]
Description=EXPRESSCLUSTER Witness Server
After=syslog.target network.target

[Service]
Type=simple
ExecStart=/usr/bin/clpwitnessd
WorkingDirectory=/opt/clpwitnessd
KillMode=process
Restart=always

[Install]
WantedBy=multi-user.target
```

3. Execute systemctl command to register and start the Witness server service.

```
# systemctl enable clpwitnessd
# systemctl start clpwitnessd
```

## EXPRESSCLUSTER COMMAND REFERENCE

This chapter describes commands that are used on EXPRESSCLUSTER.

This chapter covers:

- 8.1. *Operating the cluster from the command line*
- 8.2. *EXPRESSCLUSTER commands*
- 8.3. *Displaying the cluster status (clpstat command)*
- 8.4. *Operating the cluster (clpcl command)*
- 8.5. *Shutting down a specified server (clpdown command)*
- 8.6. *Shutting down the entire cluster (clpstdn command)*
- 8.7. *Operating groups (clpgrp command)*
- 8.8. *Collecting logs (clplogcc command)*
- 8.9. *Changing, backing up, and checking cluster configuration data (clpcfctrl command)*
- 8.10. *Adjusting time-out temporarily (clptoratio command)*
- 8.11. *Modifying the log level and size (clplogcf command)*
- 8.12. *Managing licenses (clplcns command)*
- 8.13. *Locking disk I/O (clproset command)*
- 8.14. *Mirror-disk-related commands*
  - 8.14.1. *Displaying the mirror status (clpmdstat command)*
  - 8.14.2. *Operating mirror disk resource (clpmdctrl command)*
  - 8.14.3. *Initializing mirror disks (clpmdinit command)*
  - 8.14.4. *Preparing for backup to a disk image (clpbackup.sh command)*
  - 8.14.5. *Perform the processing after restoring from a disk image (clprestore.sh command)*
- 8.15. *Hybrid-disk-related commands*
  - 8.15.1. *Displaying the hybrid disk status (clphdstat command)*
  - 8.15.2. *Operating hybrid disk resource (clphdctrl command)*
  - 8.15.3. *Initializing hybrid disks (clphdinit command)*
  - 8.15.4. *Preparing for backup to a disk image (clpbackup.sh command)*
  - 8.15.5. *Perform the processing after restoring from a disk image (clprestore.sh command)*

- 8.16. *Outputting messages (clplogcmd command)*
- 8.17. *Controlling monitor resources (clpmonctrl command)*
- 8.18. *Controlling group resources (clprsc command)*
- 8.19. *Controlling reboot count (clpregctrl command)*
- 8.20. *Turning off warning light (clplamp command)*
- 8.21. *Controlling CPU frequency (clpcpufreq command)*
- 8.22. *Controlling chassis identify lamp (clpledctrl command)*
- 8.23. *Processing inter-cluster linkage (clptrnreq command)*
- 8.24. *Requesting processing to cluster servers (clprexec command)*
- 8.25. *Changing BMC information (clpbmccnf command)*
- 8.26. *Controlling cluster activation synchronization wait processing (clpbwctrl command)*
- 8.27. *Estimating the amount of resource usage (clpprer command)*
- 8.28. *Checking the process health (clphealthchk command)*
- 8.29. *Controlling the rest point of DB2 (clpdb2still command)*
- 8.30. *Controlling the rest point of MySQL (clpmysqlstill command)*
- 8.31. *Controlling the rest point of Oracle (clporclstill command)*
- 8.32. *Controlling the rest point of PostgreSQL (clppsycopgstill command)*
- 8.33. *Controlling the rest point of SQL Server (clpmssqlstill command)*
- 8.34. *Controlling the rest point of Sybase (clpsybasestill command)*
- 8.35. *Displaying the cluster statistics information (clpperfc command)*
- 8.36. *Checking the cluster configuration information (clpcfchk command)*
- 8.37. *Creating a cluster configuration data file (clpcfset command)*
- 8.38. *Performing encryption (clpencrypt command)*

## 8.1 Operating the cluster from the command line

EXPRESSCLUSTER provides various commands to operate a cluster by the command line. These commands are useful for things like constructing a cluster or when you cannot use the Cluster WebUI. You can perform greater number of operations using the command line than Cluster WebUI.

---

**Note:** When you have configured a group resource (examples: disk resource and exec resource) as a recovery target in the settings of error detection by a monitor resource, and the monitor resource detects an error, do not perform the following actions by commands related to the actions or by the Cluster WebUI while recovery (reactivation -> failover -> final action) is ongoing.

- terminate/suspend the cluster
- start/terminate/migrate a group

If you perform the actions mentioned above against the cluster while the recovery caused by detection of an error by a monitor resource is ongoing, other group resources of that group may not terminate. However, you can perform these actions as long as the final action has been executed, even if a monitor resource detected an error.

---

---

**Important:** The installation directory contains executable-format files and script files that are not listed in this guide. Do not execute these files by programs or applications other than EXPRESSCLUSTER. Any problems caused by not using EXPRESSCLUSTER will not be supported.

## 8.2 EXPRESSCLUSTER commands

### Commands for configuring a cluster

Command	Description	Page
clpcfctrl	Distributes configuration data created by the Cluster WebUI to servers.  Backs up the cluster configuration data to be used by the Cluster WebUI.	8.9.
clplnsc	Manages the product or trial version license of this product.	8.12.
clpcfchk	Checks the cluster configuration data.	8.36.
clpcfset	Creates a cluster configuration data file.	8.37.
clpencrypt	Encrypts a character string.	8.38.

### Commands for displaying status

Command	Description	Page
clpstat	Displays the cluster status and configuration information.	8.3.
clphealthchk	Check the process health.	8.28.

### Commands for cluster operation

Command	Description	Page
clpcl	Starts, stops, suspends, or resumes the EXPRESSCLUSTER daemon.	8.4.
clpdown	Stops the EXPRESSCLUSTER daemon and shuts down the server.	8.5.
clpstdn	Stops the EXPRESSCLUSTER daemon across the whole cluster and shuts down all servers.	8.6.
clpgrp	Starts, stops, or moves groups. This command also migrates the virtual machine.	8.7.
clptoratio	Extends or displays the various time-out values of all servers in the cluster.	8.10.
clproset	Modifies and displays I/O permission of a shared disk partition device.	8.13.
clpmonctrl	Controls monitor resources.	8.17.
clpregctrl	Displays or initializes the reboot count on a single server.	8.19.
clprsc	Stops or resumes group resources	8.18.
clpcpufreq	Controls CPU frequency.	8.21.
clpledctrl	Controls the chassis identify function.	8.22.
clptrnreq	Requests a server to execute a process.	8.23.
clprexec	Requests that an EXPRESSCLUSTER server execute a process from external monitoring.	8.24.
clpbmccnf	Changes the information on BMC user name and password.	8.25.
clpbwctrl	Controls the cluster activation synchronization wait processing.	8.26.

### Log-related commands

Command	Description	Page
clplogcc	Collects logs and OS information.	8.8.
clplogcf	Modifies and displays a configuration of log level and the file size of log output.	8.11.
clpperfc	Displays the cluster statistics data about groups and monitor resources.	8.35.

#### **Script-related commands**

Command	Description	Page
clplogcmd	Writes texts in the exec resource script to create a desired message to the output destination	8.16.

#### **Mirror-related commands (when the Replicator is used)**

Command	Description	Page
clpmdstat	Displays a mirroring status and configuration information.	8.14.1.
clpmdctrl	Executes various operations such as mirror recovery and the activation/deactivation of mirror disk resources. Displays or modifies the maximum number of the request queues.	8.14.2.
clpmdinit	Initializes the cluster partition of a mirror disk resource. Creates a file system on the data partition of a mirror disk resource.	8.14.3.
clpbackup.sh	Allows a partition to be mirrored to be backed up to a disk image.	8.14.4.
clprestore.sh	Allows a restored mirror disk image to be enabled.	8.14.5.

#### **Hybrid disk-related commands (when the Replicator DR is used)**

Command	Description	Page
clphdstat	Displays the hybrid disk status and configuration information.	8.15.1.
clphdctrl	Executes various operations such as mirror recovery and the activation/deactivation of hybrid disk resources. Displays or modifies the maximum number of the request queues.	8.15.2.
clphdinit	Initializes the cluster partition of a hybrid disk resource.	8.15.3.
clpbackup.sh	Allows a partition to be mirrored to be backed up to a disk image.	8.15.4.
clprestore.sh	Allows a restored mirror disk image to be enabled.	8.15.5.

#### **System monitor-related commands (when the System Resource Agent is used)**

Command	Description	Page
clpprer	Estimates the future value from the tendency of the given resource use amount data.	<a href="#">8.27.</a>

#### **DB rest point-related commands**

Command	Description	Page
clpdb2still	Controls the securing/release of the rest point of DB2.	<a href="#">8.29.</a>
clpmysqlstill	Controls the securing/release of the rest point of MySQL.	<a href="#">8.30.</a>
clporclstill	Controls the securing/release of the rest point of Oracle.	<a href="#">8.31.</a>
clppsqlstill	Controls the securing/release of the rest point of PostgreSQL.	<a href="#">8.32.</a>
clpmssqlstill	Controls the securing/release of the rest point of SQL Server.	<a href="#">8.33.</a>
clpsybasestill	Controls the securing/release of the rest point of Sybase.	<a href="#">8.34.</a>

#### **Other commands**

Command	Description	Page
clplamp	Lights off the warning light of the specified server.	<a href="#">8.20.</a>

## 8.3 Displaying the cluster status (clpstat command)

the clpstat command displays cluster status and configuration information.

### Command line

```
clpstat -s [--long] [-h hostname]  
clpstat -g [-h hostname]  
clpstat -m [-h hostname]  
clpstat -n [-h hostname]  
clpstat -p [-h hostname]  
clpstat -i [--detail] [-h hostname]  
clpstat --cl [--detail] [-h hostname]  
clpstat --sv [server_name] [--detail] [-h hostname]  
clpstat --hb [hb_name] [--detail] [-h hostname]  
clpstat --np [np_name] [--detail] [-h hostname]  
clpstat --svg [servergroup_name] [--detail] [-h hostname]  
clpstat --grp [group_name] [--detail] [-h hostname]  
clpstat --rsc [resource_name] [--detail] [-h hostname]  
clpstat --mon [monitor_name] [--detail] [-h hostname]  
clpstat --xcl [xclname] [--detail] [-h hostname]  
clpstat --local
```

### Description

This command line displays a cluster status and configuration data.

### Option

**-s**

**No** *option*

Displays a cluster status.

**--long**

Displays a name of the cluster name and resource name until the end.

**-g**

Displays a cluster group map.

**-m**

Displays status of each monitor resource on each server.

**-n**

Displays each heartbeat resource status on each server.

**-p**

Displays the status of network partition resolution resource on each server.

**-i**

Displays the configuration information of the whole cluster.

**--cl**

Displays the cluster configuration data. Displays the Mirror Agent information as well for the Replicator, Replicator DR.

- sv** [server\_name]  
Displays the server configuration information. By specifying the name of a server, you can display information of the specified server.
- hb** [hb\_name]  
Displays heartbeat resource configuration information. By specifying the name of a heartbeat resource, you can display only the information on the specified heartbeat.
- np** [np\_name]  
Displays network partition resolution resource configuration information. By specifying the name of a network partition resolution resource, you can display only the information on the specified network partition resolution resource.
- svg** [servergroup\_name]  
Displays server group configuration information. By specifying the name of a server group, you can display only the information on the specified server group.
- rsc** [resource\_name]  
Displays group resource configuration information. By specifying the name of a group resource, you can display only the information on the specified group resource.
- mon** [monitor\_name]  
Displays monitor resource configuration information. By specifying the name of a monitor resource, you can display only the information on the specified resource.
- xcl** [xclname]  
Displays configuration information of exclusion rules. By specifying exclusion rule name, only the specified exclusion name information can be displayed.
- detail**  
Displays more detailed information on the setting.
- h** hostname  
Acquires information from the server specified with *hostname*. Acquires information from the command running server (local server) when the -h option is omitted.
- local**  
Displays the cluster status. This option displays the same information when -s option is specified or when no option is specified. However, this option displays only information of the server on which this command is executed, without communicating with other servers.

#### Return Value

When the -s option is not specified

0	Success
9	The command was run duplicatedly.
Other than the above	Failure

#### Remarks

According to the combination of options, configuration information shows information in various forms.

"\*" alongside the server name, displayed after executing this command, represents the server that executed this command.

#### Notes

- Run this command as the root user.
- This command cannot be double launched.
- When you specify the name of a server for the -h option, the server should be in the cluster.

- For the language used for command output, see "*Cluster properties - Info tab*" in "*2. Parameter details*" in this guide.
- When you run the clpstat command with the -s option or without any option, names such as a cluster or a resource will not be displayed halfway.

**Example of Execution**

Examples of information displayed after running these commands are provided in the next topic.

**Error Messages**

Message	Cause/Solution
Log in as root.	Log on as the root user.
Invalid configuration file. Create valid cluster configuration data.	Create valid cluster configuration data by using the Cluster WebUI.
Invalid option.	Specify a valid option.
Could not connect to the server. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Invalid server status.	Check if the cluster daemon is started.
Server is not active. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Invalid server name. Specify a valid server name in the cluster.	Specify the valid name of a server in the cluster.
Invalid heartbeat resource name. Specify a valid heartbeat resource name in the cluster.	Specify the valid name of a heartbeat resource in the cluster.
Invalid network partition resource name. Specify a valid network partition resource name in the cluster.	Specify the valid name of a network partition resolution resource in the cluster.
Invalid group name. Specify a valid group name in the cluster.	Specify the valid name of a group in the cluster.
Invalid group resource name. Specify a valid group resource name in the cluster.	Specify the valid name of a group resource in the cluster.
Invalid monitor resource name. Specify a valid monitor resource name in the cluster.	Specify the valid name of a monitor resource in the cluster.
Connection was lost. Check if there is a server where the cluster daemon is stopped in the cluster.	Check if there is any server on which the cluster daemon has stopped in the cluster.
Invalid parameter.	The value specified as a command parameter may be invalid.
Internal communication timeout has occurred in the cluster server. If it occurs frequently, set the longer timeout.	A time-out occurred in the EXPRESSCLUSTER internal communication. If time-out keeps occurring, set the internal communication time-out longer.
Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.
Invalid server group name. Specify a valid server group name in the cluster.	Specify the correct server group name in the cluster.
The cluster is not created.	Create and apply the cluster configuration data.

Continued on next page

Table 8.11 – continued from previous page

Message	Cause/Solution
Could not connect to the server. Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.
Cluster is stopped. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Cluster is suspended. To display the cluster status, use --local option.	Cluster is suspended. To display the cluster status, use --local option.

### 8.3.1 Common entry examples

### 8.3.2 Displaying the status of the cluster (-s option)

The following is an example of display when you run the clpstat command with the -s option or without any option:

**Example of a command entry**

```
# clpstat -s
```

**Example of the display after running the command**

```
===== CLUSTER STATUS =====
Cluster : cluster
<server>
*server1.....: Online server1
  lanhb1       : Normal LAN Heartbeat
  lanhb2       : Normal LAN Heartbeat
  diskhb1      : Normal Disk Heartbeat
  comhb1       : Normal COM Heartbeat
  witnesshb1   : Normal Witness Heartbeat
  pingnp1      : Normal ping resolution
  pingnp2      : Normal ping resolution
  httpnp1      : Normal http resolution

server2.....: Online server2
  lanhb1       : Normal LAN Heartbeat
  lanhb2       : Normal LAN Heartbeat
  diskhb1      : Normal Disk Heartbeat
  comhb1       : Normal COM Heartbeat
  witnesshb1   : Normal Witness Heartbeat
  pingnp1      : Normal ping resolution
  pingnp2      : Normal ping resolution
  httpnp1      : Normal http resolution

<group>
failover1.....: Online failover group1
  current      : server1
  disk1        : Online /dev/sdb5
  exec1        : Online exec resource1
  fip1         : Online 10.0.0.11
failover2.....: Online failover group2
  current      : server2
  disk2        : Online /dev/sdb6
  exec2        : Online exec resource2
  fip2         : Online 10.0.0.12
<monitor>
```

(continues on next page)

(continued from previous page)

```

diskw1      : Normal disk monitor1
diskw2      : Normal disk monitor2
ipw1        : Normal ip monitor1
pidw1       : Normal pidw1
userw       : Normal usermode monitor
sraw        : Normal sra monitor
=====

```

Information on each status is provided in "*Status Descriptions*".

### 8.3.3 Displaying a group map (-g option)

To display a group map, run the clpstat command with the -g option.

#### Example of a command entry

```
# clpstat -g
```

#### Example of the display after running the command

```

===== GROUPMAP INFORMATION =====
Cluster : cluster
*server0 : server1
  server1 : server2
-----
server0 [o] : failover1[o] failover2[o]
server1 [o] : failover3[o]
=====

```

- Groups that are not running are not displayed.
- Information on each status is provided in "*Status Descriptions*".

### 8.3.4 Displaying the status of monitor resources (-m option)

To display the status of monitor resources, run the clpstat command with the -m option.

#### Example of a command entry

```
# clpstat -m
```

#### Example of the display after running the command

```

===== MONITOR RESOURCE STATUS =====
Cluster : cluster
*server0 : server1
  server1 : server2
Monitor0 [diskw1 : Normal]
-----
server0 [o] : Online
server1 [o] : Online
Monitor1 [diskw2 : Normal]
-----
server0 [o] : Online
server1 [o] : Online

```

(continues on next page)

(continued from previous page)

```

Monitor2 [ipwl : Normal]
-----
server0 [o] : Online
server1 [o] : Online
Monitor3 [pidwl : Normal]
-----
server0 [o] : Online
server1 [o] : Offline
Monitor4 [userw : Normal]
-----
server0 [o] : Online
server1 [o] : Online
Monitor5 [sraw : Normal]
-----
server0 [o] : Online
server1 [o] : Online
=====

```

Information on each status is provided in "*Status Descriptions*".

### 8.3.5 Displaying the status of heartbeat resources (-n option)

To display the status of heartbeat resources, run clpstat command with the -n option.

**Example of a command entry**

```
# clpstat -n
```

**Example of the display after running the command**

```

===== HEARTBEAT RESOURCE STATUS =====
Cluster : cluster
*server0 : server1
server1 : server2
HB0 : lanhb1
HB1 : lanhb2
HB2 : diskhb1
HB3 : comhb1
HB4 : witnesshb1

[on server0 : Online]
HB  0 1 2 3 4
-----
erver0 : o o o o o
server1 : o o o x o

[on server1 : Online]
HB  0 1 2 3 4
-----
server0 : o o o x o
server1 : o o o o o
=====

```

Detailed information on each status is provided in "*Status Descriptions*".

**The status of the example shown above**

The example above presents the status of all heartbeat resources seen from server0 and server1 when the COM

heartbeat resource is disconnected.

Because comhb1, a COM heartbeat resource, is not able to communicate from both servers, communication to server1 on server0 or communication to server0 on server1 is unavailable.

The rest of heartbeat resources on both servers are in the status allowing communications.

### 8.3.6 Displaying the status of network partition resolution resources (-p option)

To display the status of network partition resolution resources, run clpstat command with the -p option.

#### Example of a command entry

```
# clpstat -p
```

#### Example of the display after running the command

```
===== NETWORK PARTITION RESOURCE STATUS =====
Cluster : cluster
*server0 : server1
  server1 : server2
  NP0 : pingnp1
  NP1 : pingnp2
  NP2 : httpnp1

  [on server0 : Caution]
    NP    0 1 2
-----

server0 : o x o
server1 : o x o

  [on server1 : Caution]
    NP    0 1 2
-----

server0 : o x o
server1 : o x o
=====
```

Detailed information on each status is provided in "[Status Descriptions](#)".

#### The status of the example shown above

The example above presents the status of all the network partition resolution resources seen from server0 and server1 when the device to which ping of the network partition resolution resource pingnp2 is sent is down.

### 8.3.7 Displaying the cluster configuration data (--cl option)

To display the configuration data of a cluster, run the clpstat command with the -i, --cl, --svg, --hb, --grp, --rsc, --mon, or --xcl option. You can see more detailed information by specifying the --detail option.

For details of each item of the list, see "[Cluster properties](#)" in "[2. Parameter details](#)" in this guide.

To display the cluster configuration data, run the clpstat command with the --cl option.

#### Example of a command entry

```
# clpstat --cl
```

#### Example of the display after running the command

```
===== CLUSTER INFORMATION =====  
[Cluster : cluster]  
Comment  : failover cluster  
=====
```

### 8.3.8 Displaying only the configuration data of certain servers (--sv option)

When you want to display only the cluster configuration data on a specified server, specify the name of the server after the --sv option in the clpstat command. If you want to see the details, specify the --detail option. When the name of the server is not specified, cluster configuration data of all servers are displayed.

**Example of a command entry**

```
# clpstat --sv server1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====  
[Server0 : server1]  
Comment           : server1  
Virtual Infrastructure : vSphere  
Product           : EXPRESSCLUSTER X 4.3 for Linux  
Internal Version   : 4.3.0-1  
Edition           : X  
Platform          : Linux  
=====
```

### 8.3.9 Displaying only the resource information of certain heartbeats (--hb option)

When you want to display only the cluster configuration data on a specified heartbeat resource, specify the name of the heartbeat resource after the --hb option in the clpstat command. If you want to see the details, specify the --detail option.

**Example of a command entry**

For a LAN heartbeat resource:

```
# clpstat --hb lanhb1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====  
[HB0 : lanhb1]  
Type              : lanhb  
Comment           : LAN Heartbeat  
=====
```

**Example of a command entry**

For disk heartbeat resource:

```
# clpstat --hb diskhb
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[HB2 : diskhb1]
Type           : diskhb
Comment        : Disk Heartbeat
=====
```

**Example of a command entry**

For COM heartbeat resource:

```
# clpstat --hb comhb
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[HB3 : comhb1]
Type           : comhb
Comment        : COM Heartbeat
=====
```

**Example of a command entry**

For kernel mode LAN heartbeat resource:

```
# clpstat --hb lankhb
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[HB4 : lankhb1]
Type           : lankhb
Comment        : Kernel Mode LAN Heartbeat
=====
```

**Example of a command entry**

For a BMC heartbeat resource:

```
# clpstat --hb bmchb1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[HB0 : bmchb1]
Type           : bmchb
Comment        : BMC Heartbeat
=====
```

**Tips**

By using the --sv option and the --hb option together, you can see the information as follows.

**Example of a command entry**

```
# clpstat --sv --hb
```

**Example of the display after running the command:**

```
===== CLUSTER INFORMATION =====
[Server0 : server1]
Comment        : server1

### 8.3.10 Displaying only the configuration data of certain network partition resolution resources (--np option)

When you want to display only the cluster configuration data on the specified network partition resolution resource, specify the name of the network partition resolution resource after the --np option in the clpstat command. If you want to see the details, specify the --detail option. When you do not specify the name of the network partition resolution resource, the cluster configuration data of all the network partition resolution resources is displayed.

#### Example of a command entry

For a PING network partition resolution resource:

```
# clpstat --np pingnp1
```

#### Example of the display after running the command

```
===== CLUSTER INFORMATION =====
[NP0 : pingnp1]
  Type           : pingnp
  Comment        : ping resolution
=====
```

**Example of a command entry**

For a HTTP network partition resolution resource:

```
# clpstat --np httpnp1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[NP0 : httpnp1]
  Type           : httpnp
  Comment        : http resolution
=====
```

**8.3.11 Displaying only the configuration data of certain server group (--svg option)**

To display only the cluster configuration data on a specified server group, specify the name of server group after --svg option in the clpstat command. When you do not specify the name of server group, the cluster configuration data of all the server groups is displayed.

**Example of a command entry**

```
# clpstat --svg servergroup1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[ServerGroup0 : servergroup1]
  server0       : server1
  server1       : server2
  server2       : server3
=====
```

**8.3.12 Displaying only the configuration data of certain groups (--grp option)**

When you want to display only the cluster configuration data on a specified group, specify the name of the group after the --grp option in the clpstat command. If you want to see the details, specify the --detail option. When you do not specify the name of group, the cluster configuration data of all the groups is displayed.

**Example of a command entry**

```
# clpstat --grp failover1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[Group0 : failover1]
  Type           : failover
```

(continues on next page)

(continued from previous page)

```
Comment          : failover group1
=====
```

### 8.3.13 Displaying only the configuration data of a certain group resource (--rsc option)

When you want to display only the cluster configuration data on a specified group resource, specify the group resource after the --rsc option in the clpstat command. If you want to see the details, specify the --detail option. When you do not specify the name of server group, the cluster configuration data of all the group resources is displayed.

#### Example of a command entry

For floating IP resource:

```
# clpstat --rsc fip1
```

#### Example of the display after running the command

```
===== CLUSTER INFORMATION =====
[Resource2 : fip1]
  Type           : fip
  Comment        : 10.0.0.11
  IP Address     : 10.0.0.11
=====
```

#### Tips

By using the --grp option and the --rsc option together, you can display the information as follows.

#### Example of a command entry

```
# clpstat --grp --rsc
```

#### Example of the display after running the command

```
===== CLUSTER INFORMATION =====
[Group0 : failover1]
  Type           : failover

Comment             : exec resource2
Start Script Path    : /opt/userpp/start2.sh
Stop Script Path     : /opt/userpp/stop2.sh
[Resource2 : fip2]
Type                : fip
Comment             : 10.0.0.12
IP Address           : 10.0.0.12
=====

```

### 8.3.14 Displaying only the configuration data of a certain monitor resource (--mon option)

When you want to display only the cluster configuration data on a specified monitor resource, specify the name of the monitor resource after the --mon option in the clpstat command. If you want to see the details, specify --detail option. When you do not specify the name of monitor resource, the cluster configuration data of all monitor resources is displayed.

#### Example of a command entry

For floating IP monitor resource:  
# clpstat --mon fipw1

**Example of the display after running the command:**

```

===== CLUSTER INFORMATION =====
[Monitor2 : fipw1]
Type                : fipw
Comment             : fip monitor1
=====

```

### 8.3.15 Displaying the configuration data of a resource specified for an individual server (--rsc option or --mon option)

When you want to display the configuration data on a resource specified for an individual server, specify the name of the resource after the --rsc or --mon option in the clpstat command.

#### Example of a command entry

When the monitor target IP address of the IP monitor resource is set to an individual server:  
# clpstat --mon ipw1

**Example of the display after running the command:**

```
===== CLUSTER INFORMATION =====
[Monitor2 : ipw1]
  Type           : ipw
  Comment        : ip monitor1
  IP Addresses   : Refer to server's setting
<server1>
  IP Addresses   : 10.0.0.253
                  : 10.0.0.254
<server2>
  IP Addresses   : 10.0.1.253
                  : 10.0.1.254
=====
```

### 8.3.16 Displaying only the configuration data of specific exclusion rules (--xcl option)

When you want to display only the cluster configuration data on a specified exclusion rules, specify the exclusive rule name after the --xcl option in the clpstat command.

**Example of a command entry**

```
# clpstat --xcl excl1
```

**Example of the display after running the command**

```
===== CLUSTER INFORMATION =====
[Exclusive Rule0 : excl1]
  Exclusive Attribute : Normal
  group0             : failover1
  group1             : failover2
=====
```

### 8.3.17 Displaying all configuration data (-i option)

By specifying the -i option, you can display the configuration information that is shown when --cl, --sv, --hb, --svg, --grp, --rsc, --mon, and --xcl options are all specified.

If you run the command with the -i option and the --detail option together, all the detailed cluster configuration data is displayed. Because this option displays large amount of information at a time, use a command, such as the less command, and pipe, or redirect the output in a file for the output.

**Tips**

Specifying the -i option displays all the information on a console. If you want to display some of the information, it is useful to combine the --cl, --sv, --hb, --svg, --grp, --rsc, and/or --mon option. For example, you can use these options as follows:

**Example of a command entry**

If you want to display the detailed information of the server whose name is "server0," the group whose name is "failover1," and the group resources of the specified group, enter:

```
# clpstat --sv server0 --grp failover1 --rsc --detail
```

### 8.3.18 Displaying the status of the cluster (--local option)

By specifying the --local option, you can display only information of the server on which you execute the clpstat command, without communicating with other servers.

#### Example of a command entry

```
# clpstat --local
```

#### Example of the display after running the command

```

===== CLUSTER STATUS =====

	-	Status unknown

## 8.4 Operating the cluster (clpcl command)

the clpcl command operates a cluster

### Command line

```
clpcl -s [-a] [-h hostname]  
clpcl -t [-a] [-h hostname] [-w timeout] [--apito timeout]  
clpcl -r [-a] [-h hostname] [-w timeout] [--apito timeout]  
clpcl --suspend [--force] [-w timeout] [--apito timeout]  
clpcl --resume
```

### Description

This command starts, stops, suspends, or resumes the cluster daemon.

### Option

- s**  
Starts the cluster daemon.
- t**  
Stops the cluster daemon.
- r**  
Restarts the cluster daemon.
- suspend**  
Suspends the entire cluster
- w *timeout***  
clpcl command specifies the wait time to stop or suspend the cluster daemon to be completed when -t, -r, or --suspend option is used. The unit of time is second.  
  
When a time-out is not specified, it waits for unlimited time.  
  
When "0 (zero)" is specified, it does not wait.  
  
When -w option is not specified, it waits for (heartbeat time-out x 2) seconds.
- resume**  
Resumes the entire cluster. The status of group resource of the cluster when suspended is kept.
- a**  
Executed the command on all servers
- h *hostname***  
Makes a request to run the command to the server specified in *hostname*. Makes a processing request to the server on which this command runs (local server) if the -h option is omitted.
- force**  
When used with the --suspend option, forcefully suspends the cluster regardless of the status of all the servers in the cluster.
- apito *timeout***  
  
Specify the interval (internal communication timeout) to wait for the EXPRESSCLUSTER daemon start or stop in seconds. A value from 1 to 9999 can be specified.

If the `--apito` option is not specified, waiting for the EXPRESSCLUSTER daemon start or stop is performed according to the value set to the internal communication timeout of the cluster properties.

#### Return Value

0	Success
Other than 0	Failure

#### Remarks

When this command is executed with the `-s` or `--resume` option specified, it returns control when processing starts on the target server.

When this command is executed with the `-t` or `--suspend` option specified, it returns control after waiting for the processing to complete.

When this command is executed with the `-r` option specified, it returns control when the EXPRESSCLUSTER daemon restarts on the target server after stopping once.

Run the `clpstat` command to display the started or resumed status of the EXPRESSCLUSTER daemon.

#### Notes

Run this command as the root user.

This command cannot be executed while a group is being started or stopped.

For the name of a server for the `-h` option, specify the name of a server in the cluster.

When you suspend the cluster, the cluster daemon should be started in all servers in the cluster. When the `--force` option is used, the cluster is forcefully suspended even if there is any stopped server in the cluster.

When you start up or resume the cluster, access the servers in the cluster in the order below, and use one of the paths that allowed successful access.

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN

When you resume the cluster, use the `clpstat` command to see there is no activated server in the cluster.

This command starts, stops, restarts, suspends, or resumes only the EXPRESSCLUSTER daemon. The mirror agent and the like are not started, stopped, restarted, suspended, or resumed together.

#### Example of a command entry

**Example 1:** Activating the cluster daemon in the local server

```
# clpcl -s
```

**Example 2:** Activating the cluster daemon in server1 from server0

```
# clpcl -s -h server1
```

Start server1 : Command succeeded.

If a server name is specified, the display after running the command should look similar to above.

Start *hostname* : Execution result

(If the activation fails, cause of the failure is displayed)

**Example 3:** Activating the cluster daemon in all servers

```
# clpcl -s -a
```

Start server0 : Command succeeded.

Start server1 : Performed startup processing to the active cluster daemon. When all the servers are activated, the display after running the command should look similar to above. Start *hostname* : Execution result

(If the activation fails, cause of the failure is displayed)

**Example 4:** Stopping the cluster daemon in all servers

```
# clpcl -t -a
```

If the cluster daemon stops on all the servers, it waits till the EXPRESSCLUSTER daemons stop on all the servers.

If stopping fails, an error message is displayed.

#### Error Messages

Message	Cause/Solution
Log in as root.	Log on as the root user.
Invalid configuration file. Create valid cluster configuration data.	Create valid cluster configuration data using the Cluster WebUI.
Invalid option.	Specify a valid option
Performed stop processing to the stopped cluster daemon.	The stopping process has been executed on the stopped cluster daemon.
Performed startup processing to the active cluster daemon.	The startup process has been executed on the activated cluster daemon.
Could not connect to the server. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Could not connect to the data transfer server. Check if the server has started up.	Check if the server is running.
Failed to obtain the list of nodes. Specify a valid server name in the cluster.	Specify the valid name of a server in the cluster.
Failed to obtain the daemon name.	Failed to obtain the cluster name.
Failed to operate the daemon.	Failed to control the cluster.
Resumed the daemon that is not suspended.	Performed the resume process for the HA Cluster daemon that is not suspended.
Invalid server status.	Check that the cluster daemon is started.
Server is busy. Check if this command is already run.	This command may have already been run.
Server is not active. Check if the cluster daemon is active.	Check if the cluster daemon is started.
There is one or more servers of which cluster daemon is active. If you want to perform resume, check if there is any server whose cluster daemon is active in the cluster.	When you execute the command to resume, check if there is no server in the cluster on which the cluster daemon is started.
All servers must be activated. When suspending the server, the cluster daemon need to be started on all servers in the cluster.	When you execute the command to suspend, the cluster daemon must be started in all servers in the cluster.
Resume the server because there is one or more suspended servers in the cluster.	Execute the command to resume because some server(s) in the cluster is in the suspend status.
Invalid server name. Specify a valid server name in the cluster.	Specify the valid name of a sever in the cluster.
Connection was lost. Check if there is a server where the cluster daemon is stopped in the cluster.	Check if there is any server on which the cluster daemon is stopped in the cluster.
Invalid parameter.	The value specified as a command parameter may be invalid.

Continued on next page

Table 8.19 – continued from previous page

Message	Cause/Solution
Internal communication timeout has occurred in the cluster server. If it occurs frequently, set the longer timeout.	A time-out occurred in the HA Cluster internal communication. If time-out keeps occurring, set the internal communication time-out longer.
Processing failed on some servers. Check the status of failed servers.	If stopping has been executed with all the servers specified, there is one of more servers on which the stopping process has failed. Check the status of the server(s) on which the stopping process has failed.
Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.
There is a server that is not suspended in cluster. Check the status of each server.	There is a server that is not suspended in the cluster. Check the status of each server.
Suspend %s : Could not suspend in time.	The server failed to complete the suspending process of the cluster daemon within the time-out period. Check the status of the server.
Stop %s : Could not stop in time.	The server failed to complete the stopping process of the cluster daemon within the time-out period. Check the status of the server.
Stop %s : Server was suspended. Could not connect to the server. Check if the cluster daemon is active.	The request to stop the cluster daemon was made. However the server was suspended.
Could not connect to the server. Check if the cluster daemon is active.	The request to stop the cluster daemon was made. However connecting to the server failed. Check the status of the server.
Suspend %s : Server already suspended. Could not connect to the server. Check if the cluster daemon is active.	The request to suspend the cluster daemon was made. However the server was suspended.
Event service is not started.	Event service is not started. Check it.
Mirror Agent is not started.	Mirror Agent is not started. Check it.
Event service and Mirror Agent are not started.	Event service and Mirror Agent are not started. Check them.
Some invalid status. Check the status of cluster.	The status of a group may be changing. Try again after the status change of the group is complete.
Failed to shut down the server.	Failed to shut down or reboot the server.

## 8.5 Shutting down a specified server (clpdown command)

the clpdown command shuts down a specified server.

### Command line

```
clpdown [-r] [-h hostname]
```

### Description

This command stops the cluster daemon and shuts down a server.

### Option

#### None

Shuts down a server.

#### -r

Reboots the server.

#### -h *hostname*

Makes a processing request to the server specified in *hostname*. Makes a processing request to the server on which this command runs (local server) if the -h option is omitted.

### Return Value

0	Success
Other than 0	Failure

### Remarks

This command runs the following commands internally after stopping the cluster daemon.

Without any option specified **shutdown**

With the -r option specified **reboot**

This command returns control when the group stop processing is completed.

This command shuts down the server even when the EXPRESSCLUSTER daemon is stopped.

### Notes

Run this command as the root user.

This command cannot be executed while a group is being started or stopped.

For the name of a server for the -h option, specify the name of a server in the cluster.

### Example of a command entry

**Example 1:** Stopping and shutting down the cluster daemon in the local server

```
# clpdown
```

**Example 2: Shutting down and rebooting server1 from server0**

```
# clpdown -r -h server1
```

### Error Message

See "*Operating the cluster (clpcl command)*".

## 8.6 Shutting down the entire cluster (clpstdn command)

the clpstdn command shuts down the entire cluster

### Command line

```
clpstdn [-r] [-h hostname]
```

### Description

This command stops the cluster daemon in the entire cluster and shuts down all servers.

### Option

#### None

Executes cluster shutdown.

#### -r

Executes cluster shutdown reboot.

#### -h *hostname*

Makes a processing request to the server specified in *hostname*. Makes a processing request to the server on which this command runs (local server) if the -h option is omitted.

### Return Value

0	Success
Other than 0	Failure

### Remarks

This command returns control when the group stop processing is completed.

### Notes

Run this command as the root user.

This command cannot be executed while a group is being started or stopped.

For the name of a server for the -h option, specify the name of a server in the cluster.

A server that cannot be accessed from the server that runs the command (for example, a server with all LAN heartbeat resources are off-line.) will not shut down.

### Example of a command entry

**Example 1:** Shutting down the cluster

```
# clpstdn
```

**Example 2:** Performing the cluster shutdown reboot

```
# clpstdn -r
```

### Error Message

See "*Operating the cluster (clpcl command)*".

## 8.7 Operating groups (clpgrp command)

the clpgrp command operates groups

### Command line

```
clpgrp -s [group_name] [-h hostname] [-f] [--apito timeout]
clpgrp -t [group_name] [-h hostname] [-f] [--apito timeout]
clpgrp -m [group_name] [-h hostname] [-a hostname] [--apito timeout]
clpgrp -l [group_name] [-h hostname] [-a hostname] [--apito timeout]
```

### Description

This command starts, deactivates or moves groups. This command also migrates groups.

### Option

- s** [group\_name]  
Starts groups. When you specify the name of a group, only the specified group starts up. If no group name is specified, all groups start up.
- t** [group\_name]  
Stops groups. When you specify the name of a group, only the specified group stops. If no group name is specified, all groups stop.
- m** [group\_name]  
Moves a specified group. If no group name is specified, all the groups are moved. The status of the group resource of the moved group is kept.
- l** [group\_name]  
  
Migrates the specified group. The group type must always be the migration type.  
If no group name is specified, all the active migration groups on the server are migrated.
- h** hostname  
Makes a processing request to the server specified in *hostname*. Makes a processing request to the server on which this command runs (local server) if the -h option is omitted.
- a** hostname  
Defines the server which is specified by *hostname* as a destination to which a group will be moved. When the -a option is omitted, the group will be moved according to the failover policy
- f**  
  
If you use this option with the -s option against a group activated on a remote server, it will forcefully be started on the server that requested the process.  
If this command is used with the -t option, the group will be stopped forcefully.
- n** group\_name  
Displays the name of the server on which the group has been started.
- apito** timeout  
  
Specify the interval (internal communication timeout) to wait for the group resource start or stop in seconds. A value from 1 to 9999 can be specified.

If the --apito option is not specified, waiting for the group resource start or stop is performed according to the value set to the internal communication timeout of the cluster properties.

#### **Return Value**

0	Success
Other than 0	Failure

#### **Notes**

Run this command as the root user.

The cluster daemon must be started on the server that runs this command

Specify a server in the cluster when you specify the name of server name for the -h and -a options.

Make sure to specify a group name, when you use the -m option.

If the group is moved by using the [-m] option, it is determined to be normal at the time of performing the group start process on the destination server. Please be aware that even if this command is executed successfully, the activation of the resource may fail on the server to which the group is moved. In order to check whether or not the group has started by using the return value, execute the following:

**# clpgrp -s [group\_name] [-h hostname] -f**

In order to move a group belonging to exclusion rules whose exclusion attribute is set to "Normal" by using the [-m] option, explicitly specify a server to which the group is moved by the [-a] option.

With the [-a] option omitted, moving a group fails if a group belonging to exclusion rules whose exclusion attribute is set to "Normal" is activated in all the movable servers.

#### **Example of Execution**

The following is an example of status transition when operating the groups.

Example: The cluster has two servers and two groups.

Failover policy of group

groupA server1 -> server2

groupB server2 -> server1

1. Both groups are stopped.

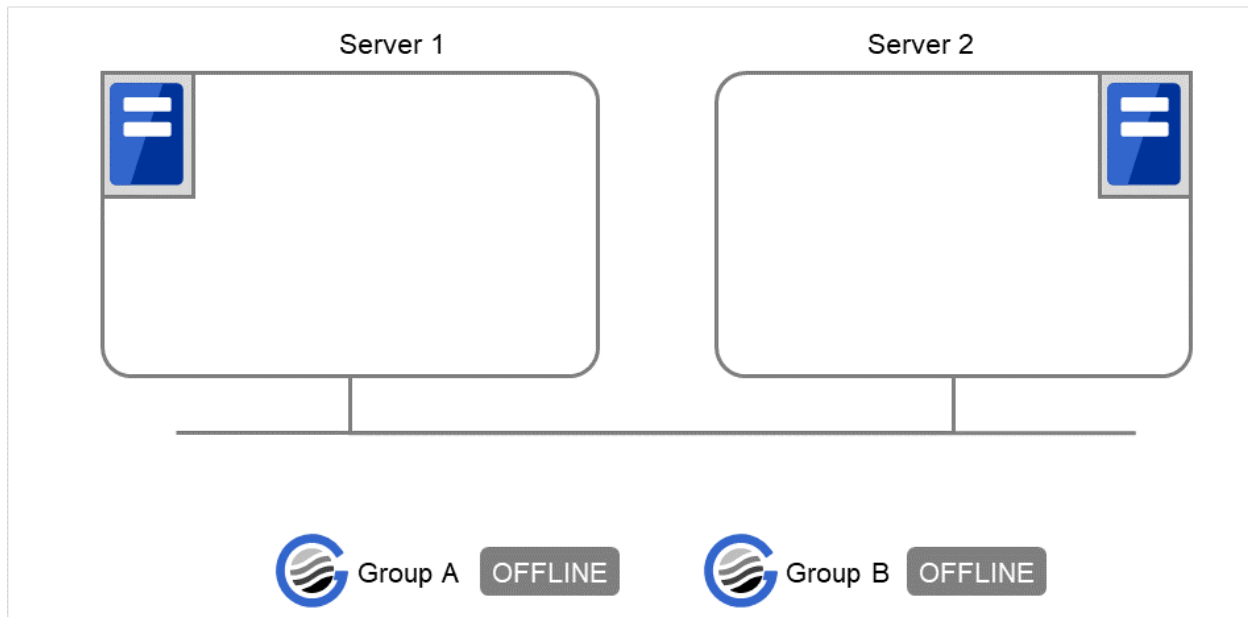

Fig. 8.1: Run-time state of the clpgrp command (1)

2. Run the following command on server1.

```
# clpgrp -s groupA
```

GroupA starts in server1.

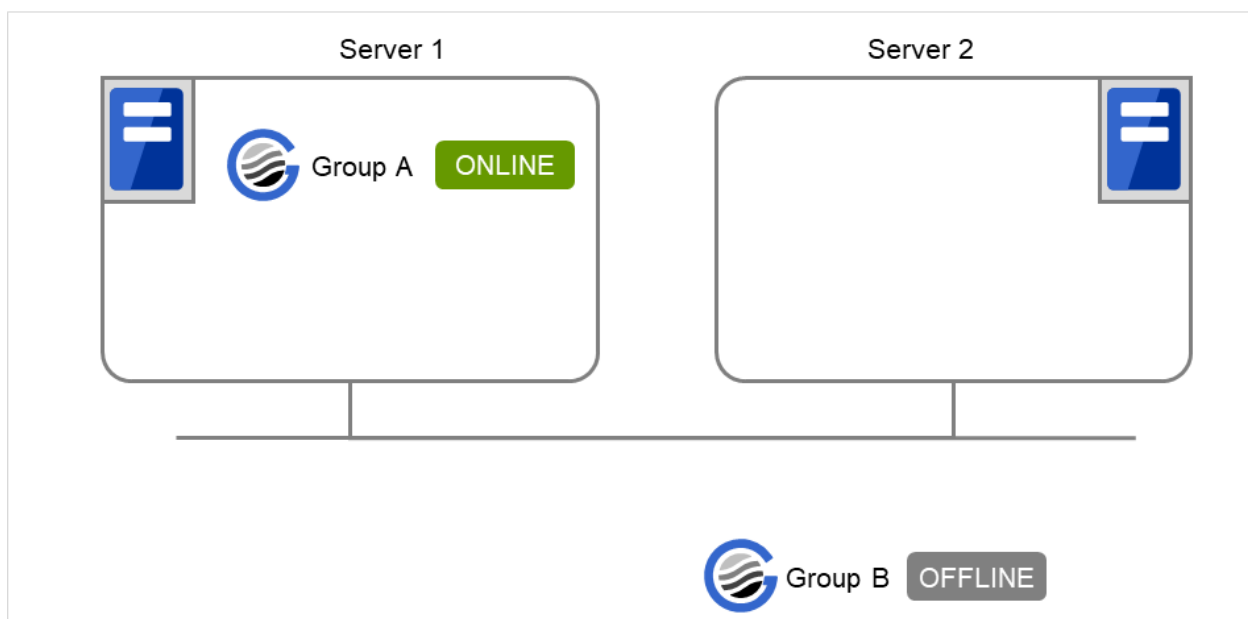

Fig. 8.2: Run-time state of the clpgrp command (2)

3. Run the following command in server2.

```
# clpgrp -s
```

All groups that are currently stopped but can be started start in server2.

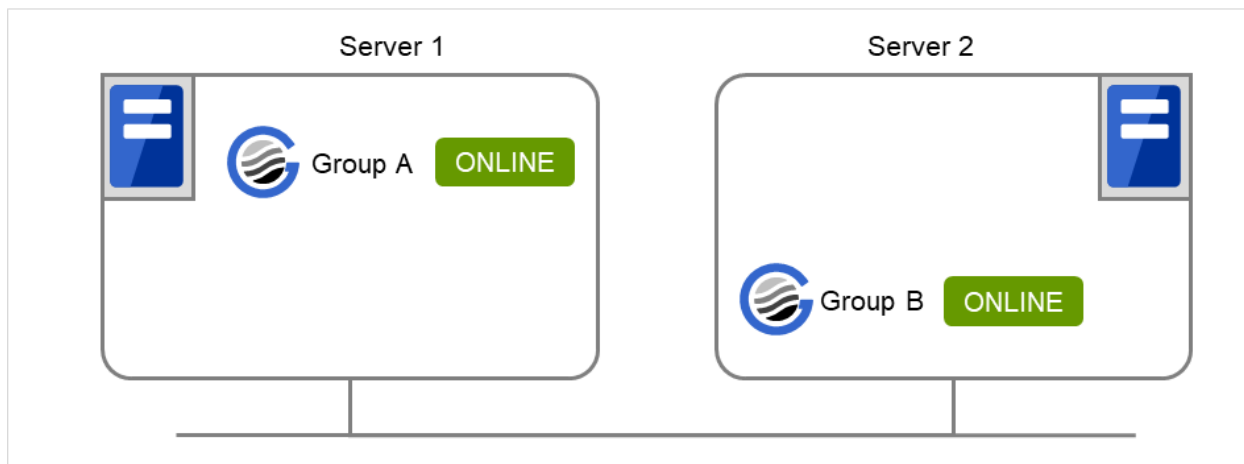

Fig. 8.3: Run-time state of the clpgrp command (3)

4. Run the following command in server1

```
# clpgrp -m groupA
```

GroupA moves to server2.

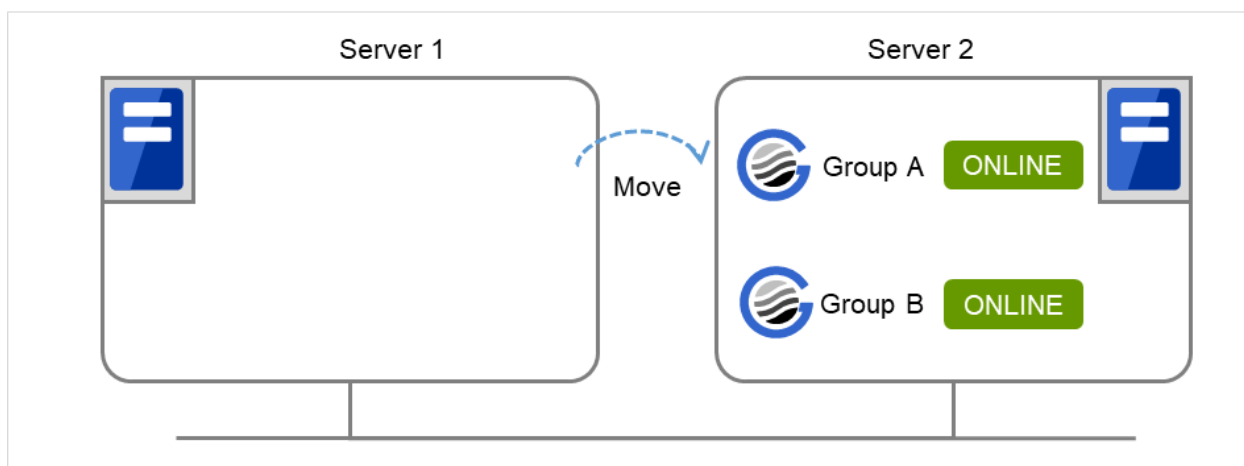

Fig. 8.4: Run-time state of the clpgrp command (4)

5. Run the following command in server1

```
# clpgrp -t groupA -h server2
```

GroupA stops.

Fig. 8.5: Run-time state of the `clpgrp` command (5)

6. Run the following command in server1.

```
# clpgrp -t  
Command Succeeded.
```

When the command is executed, there is no group running on server1. So, "Command Succeeded." appears.

7. Add `-f` to the command you have run in Step 6 and execute it on server1.

```
# clpgrp -t -f
```

Groups which were started in server2 can be forcefully deactivated from server1.

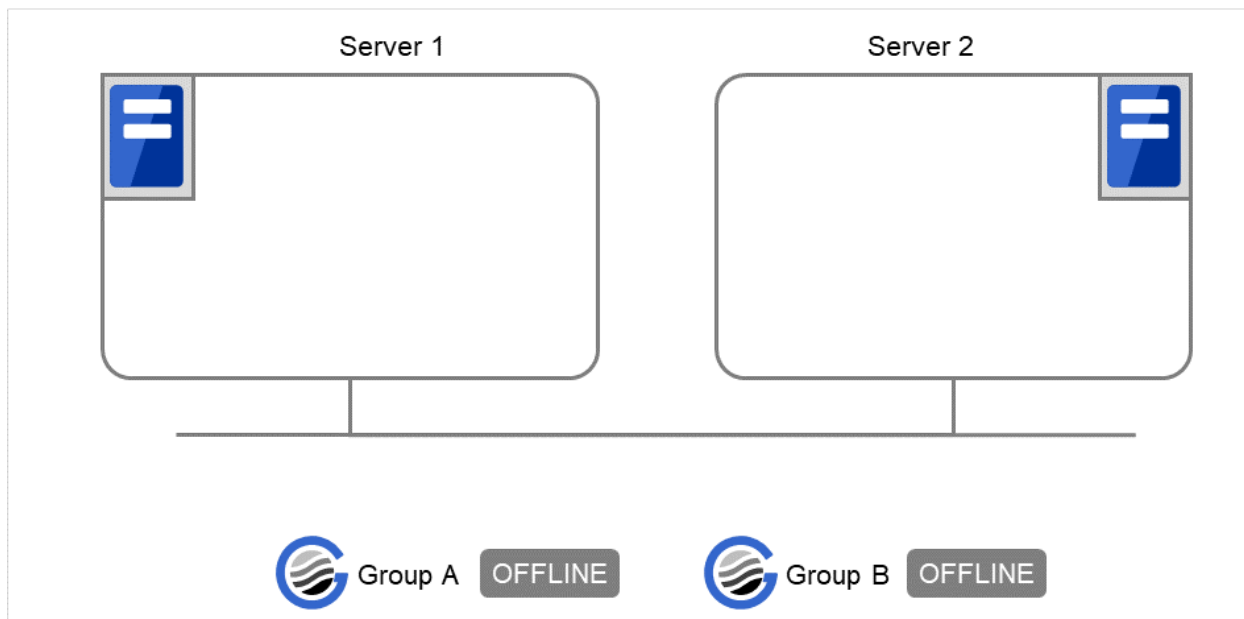

Fig. 8.6: Run-time state of the `clpgrp` command (6)

#### Error message

Message	Cause/Solution
Log in as root.	Log on as the root user.
Invalid configuration file. Create valid cluster configuration data.	Create valid cluster configuration data using the Cluster WebUI
Invalid option.	Specify a valid option
Could not connect to the server. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Invalid server status.	Check if the cluster daemon is started.
Server is not active. Check if the cluster daemon is active.	Check if the cluster daemon is started.

There is no appropriate destination for the group. Other servers are not in a condition to start group or any critical monitor error is detected.	Check the status of the server by using the Cluster WebUI or clpstat command. An error is detected in a critical monitor on all other servers.
The group has been started on the other server. To migrate the group, use "-h <hostname>" option.	Check the status of the group by using the Cluster WebUI or clpstat command. If you want to move a group which was started on a remote server, run the command with the -h host-name option.
The specified group cannot be migrated.	The specified group cannot be migrated.
The specified group is not vm group.	The specified group is not a virtual machine group.
Migration resource does not exist.	Check the status of the group by using the Cluster WebUI or clpstat command. The resource to be migrated is not found.
Migration resource is not started.	Check the status of the group by using the Cluster WebUI or clpstat command. The resource to be migrated is not started.
Some invalid status. Check the status of cluster.	Invalid status for some sort of reason. Check the status of the cluster.

Continued on next page

Table 8.20 – continued from previous page

Message	Cause/Solution
Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.

## 8.8 Collecting logs (clplogcc command)

the clplogcc command collects logs.

### Command line

```
clplogcc [ [-h hostname] | [-n targetnode1 -n targetnode2 .....] ] [-t collect_type] [-r syslog_rotate_number] [-o path] [-l]
```

### Description

This command collects information including logs and the OS information by accessing the data transfer server.

### Option

#### None

Collects logs in the cluster.

#### -h *hostname*

Specifies the name of the access destination server for collecting cluster node information

#### -t *collect\_type*

Specifies a log collection pattern. When this option is omitted, a log collection pattern will be type1. Information on log collection types is provided in "[Collecting logs by specifying a type \(-t option\)](#)".

#### -r *syslog\_rotate\_number*

Specifies how many generations of syslog will be collected. When this option is omitted, only one generation will be collected.

#### -o *path*

Specifies the output destination of collector files. When this option is skipped, logs are output under tmp of the installation path.

#### -n *targetnode*

Specifies the name of a server that collects logs. With this specification, logs of the specified server, rather than of the entire cluster, will be collected.

#### -l

Collects logs on the local server without going through the data transfer server.

The -h option and the -n option cannot be specified at the same time.

### Return Value

0	Success
Other than 0	Failure

### Remarks

Since log files are compressed by tar.gz, add the xzf option to the tar command to decompress them.

### Notes

Run this command as the root user.

For the name of server for the -h option, specify the name of a server in the cluster that allows name resolution.

For the name of server for the -n option, specify the name of server that allows name resolution. If name resolution is not possible, specify the interconnect or public LAN address.

When you run this command, access the servers in the cluster in the order below, and use one of the paths that allowed successful access.

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN
3. via the IP address whose name was resolved by the server name in the cluster configuration data

If the log files collected on Linux OS (pax format of the tar command's compression) are decompressed with guntar format of the tar command, a PaxHeaders.X folder is generated. However, it does not affect the operation.

#### **Example of command execution**

**Example 1:** Collecting logs from all servers in the cluster

```
# clplogcc
```

```
Collect Log server1 : Success
```

```
Collect Log server2 : Success
```

Log collection results (server status) of servers on which log collection is executed are displayed.

Process *hostname*: result of loc collection (server status)

#### **Execution Result**

For this command, the following processes are displayed.

Steps in Process	Meaning
Connect	Displayed when the access fails.
Get File size	Displayed when acquiring the file size fails.
Collect Log	Displayed with the file acquisition result.

The following results (server status) are displayed:

Result (server status)	Meaning
Success	Success
Timeout	Time-out occurred.
Busy	The server is busy.
Not Exist File	The file does not exist.
No Free space	No free space on the disk.
Failed	Failure caused by other errors.

#### **Error Message**

Message	Cause/Solution
Log in as root.	Log on as the root user.
Invalid configuration file. Create valid cluster configuration data.	Create valid cluster configuration data using the Cluster WebUI.
Invalid option.	Specify a valid option.
Specify a number in a valid range.	Specify a number within a valid range.
Specify a correct number.	Specify a valid number.
Specify correct generation number of syslog.	Specify a valid number for the syslog generation.
Collect type must be specified 'type1' or 'type2' or 'type3' or 'type4' or 'type5' or 'type6'. Incorrect collection type is specified.	Invalid collection type has been specified.
Specify an absolute path as the destination of the files to be collected.	Specify an absolute path for the output destination of collected files.
Specifiable number of servers are the max number of servers that can constitute a cluster.	The number of servers you can specify is within the maximum number of servers for cluster configuration.

Continued on next page

Table 8.23 – continued from previous page

Message	Cause/Solution
Could not connect to the server. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Failed to obtain the list of nodes. Specify a valid server name in the cluster.	Specify the valid name of a server in the cluster.
Invalid server status.	Check if the cluster daemon is started.
Server is busy. Check if this command is already run.	This command may have been already activated. Check the status.
Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.

### 8.8.1 Collecting logs by specifying a type (-t option)

To collect only the specified types of logs, run the `clplogcc` command with the `-t` option.

Specify a type from 1 through 6 for the log collection.

	type1	type2	type3	type4	type5	type6
1. Default collection information	✓	✓	✓	✓	n/a	n/a
2. syslog	✓	✓	✓	n/a	n/a	n/a
3. core file	✓	✓	n/a	✓	n/a	n/a
4. OS information	✓	✓	✓	✓	n/a	n/a
5. script	✓	✓	n/a	n/a	n/a	n/a
6. ESMPRO/AC	✓	✓	n/a	n/a	n/a	n/a
7. HA Logs	n/a	✓	n/a	n/a	n/a	n/a
8. Mirror statistics information	n/a	n/a	n/a	n/a	✓	n/a
9. Cluster statistics information	n/a	n/a	n/a	n/a	n/a	✓
10. System resource statistics information	✓	✓	✓	✓	n/a	✓

Run this command from the command line as follows.

Example: When collecting logs using type2

```
# clplogcc -t type2
```

When no option is specified, a log type will be type 1.

1. Information to be collected by default

Information on the following is collected by default:

- Logs of each module in the EXPRESSCLUSTER Server
- Alert logs
- Attribute of each module (ls -l) in the EXPRESSCLUSTER Server
  - In bin, lib
  - In cloud
  - In alert/bin, webmgr/bin
  - In ha/jra/bin, ha/sra/bin, ha/jra/lib, ha/sra/lib
  - In drivers/md
  - In drivers/khb
  - In drivers/ka
- All installed packages (rpm -qa expresscls execution result)
- EXPRESSCLUSTER version
- distribution (/etc/\*-release)
- License information
- Cluster configuration data file
- Policy file
- Cloud environment configuration directory
- Dump of shared memory used by EXPRESSCLUSTER
- Local node status of EXPRESSCLUSTER (clpstat --local execution results)
- Process and thread information (ps execution result)
- PCI device information (lspci execution result)
- Service information (execution results of the commands such as systemctl, chkconfig, and ls)
- Output result of kernel parameter (result of running sysctl -a)
- glibc version (rpm -qi glibc execution result)
- Kernel loadable module configuration (/etc/modules.conf. /etc/modprobe.conf)
- File system (/etc/fstab)
- IPC resource (ipcs execution result)
- System (uname -a execution result)
- Network statistics (netstat, ss execution result IPv4/IPv6)
- ip (execution results of the command ip addr, link, maddr, route or -s l)
- All network interfaces (ethtool execution result)

- Information collected at an emergency OS shutdown (See "*Collecting information when a failure occurs*".)
- libxml2 version (rpm -qi libxml2 execution result)
- Static host table (/etc/hosts)
- File system export table (exportfs -v execution result)
- User resource limitations (ulimit -a execution result)
- File system exported by kernel-based NFS (/etc/exports)
- OS locale
- Terminal session environment value (export execution result)
- Language locale (/etc/sysconfig/i18n)
- Time zone (env - date execution result)
- Work area of EXPRESSCLUSTER server
- Monitoring options  
This information is collected if options are installed.
- Collected dump information when the monitor resource timeout occurred
- Collected Oracle detailed information when Oracle monitor resource abnormality was detected

## 2. syslog

- syslog (/var/log/messages)
- syslog (/var/log/syslog)
- Syslogs for the number of generations specified (/var/log/messages.x)
- journal log (such as files in /var/run/log/journal/)

## 3. core file

- core file of EXPRESSCLUSTER module  
Stored in /opt/nec/clusterpro/log by the following archive names.

Alert related:

altyyyymmdd\_x.tar

The WebManager server related:

wmyyyymmdd\_x.tar

EXPRESSCLUSTER core related:

clsyyymmdd\_x.tar

srayyyymmdd\_x.tar

jrayyyymmdd\_x.tar

**yyymmdd** indicates the date when the logs are collected. **x** is a sequence number.

## 4. OS information

OS information on the following is collected by default:

- Kernel mode LAN heartbeat, keep alive
  - /proc/khb\_moninfo
  - /proc/ka\_moninfo

- /proc/devices
- /proc/mdstat
- /proc/modules
- /proc/mounts
- /proc/meminfo
- /proc/cpuinfo
- /proc/partitions
- /proc/pci
- /proc/version
- /proc/ksyms
- /proc/net/bond\*
- all files of /proc/scsi/ all files in the directory
- all files of /proc/ide/ all files in the directory
- /etc/fstab
- /etc/rc\*.d
- /etc/syslog.conf
- /etc/syslog-ng/syslog-ng.conf
- /etc/snmp/snmpd.conf
- Kernel ring buffer (dmesg execution result)
- ifconfig (the result of running ifconfig)
- iptables (the result of running iptables -L)
- ipchains (the result of running ipchains -L)
- df (the result of running df)
- raw device information (the result of running raw -qa)
- kernel module load information (the result of running lsmod)
- host name, domain name information (the result of running hostname, domainname)
- dmidecode (the result of running dmidecode)
- LVM device information (the result of running vgdisplay -v)
- snmpd version information (snmpd -v execution result)
- Virtual Infrastructure information (the result of running virt-what)
- blockdev (the result of running blockdev --report)

When you collect logs, you may find the following message on the console. This does not mean failure. The logs are collected normally.

```
hd#: bad special flag: 0x03  
ip_tables: (C) 2000-2002 Netfilter core team
```

(Where hd# is the name of the IDE device that exists on the server)

## 5. Script

Start/stop script for a group that was created with the Cluster WebUI.

If you specify a user-defined script other than the above (/opt/nec/clusterpro/scripts), it is not included in the log collection information. It must be collected separately.

## 6. ESMPRO/AC Related logs

Files that are collected by running the acupslog command.

## 7. HA logs

- System resource information
- JVM monitor log
- System monitor log

## 8. Mirror statistics information

- Mirror statistics information
  - In perf/disk

## 9. Cluster statistics information

- Cluster statistics information
  - In perf/cluster

## 10. System resource statistics information

- System resource statistics information
  - In perf/system

## 8.8.2 Syslog generations (-r option)

To collect syslogs for the number of generations specified, run the following command.

Example: Collecting logs for the 3 generations

```
# clplogcc -r 3
```

The following syslogs are included in the collected logs.

```
/var/log/messages
/var/log/messages.1
/var/log/messages.2
```

- When no option is specified, only /var/log/messages is collected.
- You can collect logs for 0 to 99 generations.
- When 0 is specified, all syslogs are collected.

Number of Generation	Number of generations to be acquired
0	All Generations
1	Current
2	Current + Generation 1

Continued on next page

Table 8.25 – continued from previous page

Number of Generation	Number of generations to be acquired
3	Current + Generation 1 to 2
:	
:	
x	Current + Generation 1 to (x-1)

### 8.8.3 Output paths of log files (-o option)

- Log file is named and be saved as "*server name-log.tar.gz*"
- If an IP address is specified for the -n option, a log file is named and saved as "*IP address-log.tar.gz*."
- Since log files are compressed by tar.gz, decompress them by adding the xzf option to the tar command.

#### If not specifying -o option

Logs are output in tmp of installation path.

```
# clplogcc
Collect Log hostname : Success
# ls /opt/nec/clusterpro/tmp
hostname-log.tar.gz
```

#### When the -o option is not specified:

If you run the command as follows, logs are located in the specified /home/log directory.

```
# clplogcc -o /home/log
Collect Log hostname: Success
# ls /home/log
hostname-log.tar.gz
```

### 8.8.4 Specifying log collector server (-n option)

By using the -n option, you can collect logs only from the specified server.

Example: Collecting logs from Server1 and Server3 in the cluster.

```
# clplogcc -n Server1 -n Server3
```

- Specify a server in the same cluster.
- The number of servers you can specify is within the maximum number of servers in the cluster configuration.

### 8.8.5 Collecting information when a failure occurs

When the following failure occurs, the information for analyzing the failure is collected.

- When a cluster daemon configuring the cluster abnormally terminates due to interruption by a signal (core dump) or internal status error etc.
- When a group resource activation error or deactivation error occurs
- When monitoring error occurs in a monitor resource

Information to be collected is as follows:

- Cluster information

- Some module logs in EXPRESSCLUSTER servers
  - Dump files in the shared memory used by EXPRESSCLUSTER
  - Cluster configuration information files
- OS information (/proc/\*)
  - /proc/devices
  - /proc/partitions
  - /proc/mdstat
  - /proc/modules
  - /proc/mounts
  - /proc/meminfo
  - /proc/net/bond\*
- Information created by running a command
  - Results of the sysctl -a
  - Results of the ps
  - Results of the top
  - Results of the ipcs
  - Results of the netstat -in
  - Results of the netstat -apn
  - Results of the netstat -gn
  - Results of the netstat -rn
  - Results of the ifconfig
  - Results of the ip addr
  - Results of the ip -s l
  - Results of the df
  - Results of the raw -qa
  - journalctl -e execution result

These are collected by default in the log collection. You do not need to collect them separately.

## 8.9 Changing, backing up, and checking cluster configuration data (clpcfctrl command)

### 8.9.1 Creating a cluster and changing the cluster configuration data

the clpcfctrl --push command delivers cluster configuration data to servers.

#### Command line

```
clpcfctrl --push -l-w [-h hostname|IP] [-p portnumber] [-x directory] [--force] [--nocheck]
```

#### Description

This command delivers the configuration data created by the Cluster WebUI to servers.

#### Option

##### --push

Specify this option when delivering the data. You cannot omit this option.

##### -l

Specify this option when using the configuration data saved by the Cluster WebUI on Linux.

##### -w

Specify this option when using the configuration data saved by the Cluster WebUI on Windows.  
You cannot specify -l and -w together.

##### -h *hostname* | *IP*

Specifies a server to which configuration data is delivered. Specify host name or IP address.  
If this option is omitted, configuration data is delivered to all servers.

##### -p *portnumber*

Specifies a port number of data transfer port.  
When this option is omitted, the default value will be used. In general, it is not necessary to specify this option.

##### -x *directory*

Specify this option when delivering configuration data to the specified directory.  
This option is used with -l or -w.  
When -l is specified, configuration data saved on the file system by the Cluster WebUI on Linux is used.  
When -w is specified, configuration data saved by the Cluster WebUI on Windows is used.

##### --force

Even if there is a server that has not started, the configuration data is delivered forcefully.

##### --nocheck

When this option is specified, cluster configuration data is not checked.

#### Return Value

0	Success
Other than 0	Failure

**Notes**

Run this command as the root user.

When you run this command, access the servers in the order below, and use one of the paths that allowed successful access.

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN

**Example of command execution**

**Example 1:** Delivering configuration data that was saved on the file system using the Cluster WebUI on Linux

```
# clpcfcctl --push -l -x /mnt/config
file delivery to server 10.0.0.11 success.
file delivery to server 10.0.0.12 success.
The upload is completed successfully.(cfmgr:0)
Command succeeded.(code:0)
```

**Example 2:** Delivering the configuration data to the server which has been reinstalled.

```
# clpcfcctl --push -h server2
The upload is completed successfully.(cfmgr:0)
Command succeeded.(code:0)
```

**Error Message**

## 8.9.2 Backing up the Cluster configuration data

the `clpcfctrl --pull` command backups cluster configuration data.

### Command line

```
clpcfctrl --pull -ll-w [-h hostname/IP] [-p portnumber] [-x directory]
```

### Description

This command backs up cluster configuration data to be used for the Cluster WebUI.

### Option

#### --pull

Specify this option when performing backup. You cannot omit this option.

#### -l

Specify this option when backing up configuration data that is used for the Cluster WebUI on Linux. You cannot specify both -l and -w together.

**-w**

Specify this option when backing up configuration data that is used for the Cluster WebUI on Windows.  
You cannot specify both -l and -w together.

**-h** hostname | IP

Specifies the source server for backup. Specify a host name or IP address.  
When this option is omitted, the configuration data on the server running the command is used.

**-p** portnumber

Specifies a port number of data transfer port.  
When this option is omitted, the default value is used. In general, it is not necessary to specify this option.

**-x** directory

Backs up the configuration data in the specified directory.  
Use this option with either -l or -w.  
When -l is specified, configuration data is backed up in the format which can be loaded by the Cluster WebUI on Linux.  
When -w is specified, configuration data is saved in the format which can be loaded by the Cluster WebUI on Windows.

#### Return Value

0	Success
Other than 0	Failure

#### Notes

Run this command as the root user.

When you run this command, access the servers in the cluster in the order below, and use one of the paths that allowed successful access.

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN

#### Example of command execution

**Example 1:** Backing up configuration data to the specified directory so that the data can be loaded by the Cluster WebUI on Linux

```
# clpcfctrl --pull -l -x /mnt/config  
Command succeeded. (code:0)
```

### 8.9.3 Adding a resource without stopping the group

the `clpcfctrl --dpush` command adds a resource without stopping the group.

#### Command line

```
clpcfctrl --dpush -l-w [-p portnumber] [-x directory] [--force]
```

#### Description

This command dynamically adds a resource without stopping the group.

#### Option

##### **--dpush**

Specify this option when dynamically adding a resource. You cannot omit this option.

##### **-l**

Specify this option when using the configuration data saved by the Cluster WebUI on Linux.

You cannot specify `-l` and `-w` together.

##### **-w**

Specify this option when using the configuration data saved by the Cluster WebUI on Linux.

You cannot specify `-l` and `-w` together.

##### **-p** *portnumber*

Specifies a port number of data transfer port.

When this option is omitted, the default value will be used. In general, it is not necessary to specify this option.

##### **-x** *directory*

Specify this option when delivering configuration data to the specified directory.

This option is used with `-l` or `-w`.

When `-l` is specified, configuration data saved on the file system by the Cluster WebUI on Linux is used.

When `-w` is specified, configuration data saved by the Cluster WebUI on Windows is used.

##### **--force**

Even if there is a server that has not started, the configuration data is delivered forcefully.

#### Return Value

0	Success
Other than 0	Failure

#### Notes

Run this command as the root user.

When you run this command, access the servers in the order below, and use one of the paths that allowed successful access.

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN

For details on resources that support dynamic resource addition, refer to "How to add a resource without stopping the group" in "The system maintenance information" in the "Maintenance Guide".

To use this command, the internal version of EXPRESSCLUSTER of all the nodes in the cluster must be 3.2.1-1 or later.

While the dynamic resource addition command is running, do not resume the command. Otherwise, the cluster configuration data may become inconsistent, and the cluster may stop or the server may shut down.

If you abort the dynamic resource addition command, the activation status of the resource to be added may become undefined. In this case, run the command again or reboot the cluster manually.

#### **Example of command execution**

**Example 1:** Dynamically adding a resource using configuration data that was saved on the file system using the Cluster WebUI on Linux

```
# clpcfctrl --dpush -l -x /mnt/config  
file delivery to server 10.0.0.11 success.  
file delivery to server 10.0.0.12 success.  
The upload is completed successfully.(cfmgr:0)  
Command succeeded.(code:0)
```

#### 8.9.4 Checking cluster configuration data when dynamically adding a group resource

This command checks the cluster configuration data when dynamically adding a group resource.

##### Command line

```
clpcfctrl --compcheck -ll-w [-x directory]
```

##### Description

This command checks if there is no problem with the cluster configuration data when dynamically adding a resource without stopping the group.

##### Option

###### **--compcheck**

Specify this option when checking configuration data.  
You cannot omit this option.

###### **-l**

Specify this option when using the configuration data saved by the Cluster WebUI on Linux.  
You cannot specify -l and -w together.

###### **-w**

Specify this option when using the configuration data saved by the Cluster WebUI on Linux.  
You cannot specify -l and -w together.

**-x** directory

Specify this option when delivering configuration data to the specified directory.

This option is used with -l or -w.

When -l is specified, configuration data saved on the file system by the Cluster WebUI on Linux is used.

When -w is specified, configuration data saved by the Cluster WebUI on Windows is used.

#### Return Value

0	Success
Other than 0	Failure

#### Notes

Run this command as the root user.

When you run this command, access the cluster servers in the order below, and use one of the paths that allowed successful access.

1. Via the IP address on the interconnect LAN
2. Via the IP address on the public LAN

This command finds the difference between the new and existing configuration data, and checks the resource configuration data in the added configuration data.

#### Example of command execution

**Example 1: Checking configuration data that was saved on the file system using the Cluster WebUI on Linux**

```
# clpcfcctl --compcheck -l -x /mnt/config
The check is completed successfully. (cfmgr:0)
Command succeeded. (code:0)
```

## 8.10 Adjusting time-out temporarily (clptoratio command)

the clptoratio command extends or displays the current time-out ratio.

### Command line

```
clptoratio -r ratio -t time  
clptoratio -i  
clptoratio -s
```

### Description

This command displays or temporarily extends the various time-out values of the following on all servers in the cluster.

- Monitor resource
- Heartbeat resource
- Mirror Agent
- Mirror driver
- Alert synchronous service
- WebManager service

### Option

**-r** *ratio*

Specifies the time-out ratio. Use 1 or larger integer. The maxim time-out ratio is 10,000.

If you specify "1," you can return the modified time-out ratio to the original as you can do so when you are using the -i option.

**-t** *time*

Specifies the extension period.

You can specify minutes for m, hours for h, and days for d. The maximum period of time is 30 days.

Example: 2m, 3h, 4d

**-i**

Sets back the modified time-out ratio.

**-s**

Refers to the current time-out ratio.

### Return Value

0	Success
Other than 0	Failure

### Remarks

When the cluster is shutdown, the time-out ratio you have set will become ineffective. However, if any server in the cluster is not shutdown, the time-out ratio and the extension period that you have set will be maintained.

With the -s option, you can only refer to the current time-out ratio. You cannot see other information such as remaining time of extended period.

You can see the original time-out value by using the status display command.

Heartbeat time-out

```
# clpstat --cl --detail
```

Monitor resource time-out

```
# clpstat --mon monitor resource name --detail
```

#### **Notes**

Run this command as the root user.

Make sure that the cluster daemon is started in all servers in the cluster.

When you set the time-out ratio, make sure to specify the extension period. However, if you set "1" for the time-out ratio, you cannot specify the extension period.

You cannot specify a combination such as "2m3h," for the extension period.

When the server restarts within the ratio extension period, the time-out ratio is not returned to the original even after the extension period. In this case, run the clptoratio -i command to return it to the original.

#### **Example of a command entry**

**Example 1:** Doubling the time-out ratio for three days

```
# clptoratio -r 2 -t 3d
```

**Example 2:** Setting back the time-out ratio to original

```
# clptoratio -i
```

**Example 3:** Referring to the current time-out ratio

```
# clptoratio -s
```

```
present toratio : 2
```

The current time-out ratio is set to 2.

#### **Error Message**

Message	Cause/Solution
Log in as root.	Log on as the root user.
Invalid configuration file. Create valid cluster configuration data.	Create valid cluster configuration data by using the Cluster WebUI.
Invalid option.	Specify a valid option.
Specify a number in a valid range.	Specify a number within a valid range.
Specify a correct number.	Specify a valid number.
Scale factor must be specified by integer value of 1 or more.	Specify 1 or larger integer for ratio.
Specify scale factor in a range less than the maximum scale factor.	Specify a ratio that is not larger than the maximum ratio.
Set the correct extension period.	Set a valid extension period.
Ex) 2m, 3h, 4d	Set the extension period which does not exceed the maximum ratio.
Set the extension period in a range less than the maximum extension period.	Check if the cluster daemon is started.
Could not connect to the server. Check if the cluster daemon is active.	Check if the cluster daemon is started.
Server is not active. Check if the cluster daemon is active.	Check if there is any server in the cluster with the cluster daemon stopped.

Continued on next page

Table 8.30 – continued from previous page

Message	Cause/Solution
Connection was lost. Check if there is a server where the cluster daemon is stopped in the cluster.	Check if there is any server in the cluster with the cluster daemon stopped.
Invalid parameter.	The value specified as a parameter of the command may be invalid.
Internal communication timeout has occurred in the cluster server. If it occurs frequently, set the longer timeout.	Time-out has occurred in the internal communication of EXPRESSCLUSTER. If it occurs frequently, set the internal communication time-out longer.
Processing failed on some servers. Check the status of failed servers.	There are servers that failed in processing. Check the status of server in the cluster. Operate it while all the servers in the cluster are up and running.
Internal error. Check if memory or OS resources are sufficient.	Check to see if the memory or OS resource is sufficient.

## 8.11 Modifying the log level and size (clplogcf command)

the clplogcf command modifies and displays log level and log output file size.

### Command line

`clplogcf -t type -l level -s size`

### Description

This command modifies the log level and log output file size, or displays the values currently configured.

### Option

**-t** type

Specifies a module type whose settings will be changed.

If both -l and -s are omitted, the information set to the specified module will be displayed. For the types which can be specified, see the list of "**Types that can be specified for the -t option**".

**-l** level

Specifies a log level.

You can specify one of the following for a log level.

1, 2, 4, 8, 16, 32

You can see more detailed information as the log level increases.

**-s** size

Specifies the size of a file for log output.

The unit is byte.

### None

None Displays the entire configuration information currently set.

### Return Value

0	Success
Other than 0	Failure

### Remarks

Each type of output logs from EXPRESSCLUSTER uses four log files. Therefore, it is necessary to have the disk space that is four times larger than what is specified by -s.

### Notes

Run this command as the root user.

To run this command, the EXPRESSCLUSTER event service must be started.

The changes made are effective only for the server on which this command was run.

The settings revert to the default values when the server restarts.

### Example of command execution

**Example 1:** Modifying the pm log level

```
# clplogcf -t pm -l 8
```

**Example 2:** Seeing the pm log level and log file size

```
# clplogcf -t pm
TYPE, LEVEL, SIZE
pm, 8, 1000000
```

**Example 3:** Displaying the values currently configured

```
# clplogcf
TYPE, LEVEL, SIZE
trnsv, 4, 1000000
xml, 4, 1000000
logcf, 4, 1000000
```

#### Error Message

## 8.12 Managing licenses (clplcncs command)

the clplcncs command manages licenses.

### Command line

```
clplcncs -i [licensefile...]
clplcncs -l [-a]
clplcncs -d serialno [-q]
clplcncs -d -t [-q]
clplcncs -d -a [-q]
clplcncs --distribute
clplcncs --reregister licensefile...
```

### Description

This command registers, refers to and remove the licenses of the product version and trial version of this product.

### Option

**-i** [licensefile...]

When a license file is specified, license information is acquired from the file for registration. You can specify multiple licenses. If nothing is specified, you need to enter license information interactively.

**-l** [-a]

References the registered license. The name of displayed items are as follows.

Item	Explanation
Serial No	Serial number (product version only)
User name	User name (trial version only)
Key	License key
Licensed Number of CPU	The number of license (per CPU)
Licensed Number of Computers	The number of license (per node)
Start date	Start date of valid period <sup>12</sup>
End date	End date of valid period <sup>12</sup>
Status	Status of the license

Status	Explanation
valid	valid
invalid	invalid
unknown	unknown
inactive	Before valid period <sup>12</sup>
expired	After valid period <sup>12</sup>

When -a option not specified, the license status of "invalid", "unknown" and "expired" are not displayed.

When specifying -a option, all the licenses are displayed regardless of the license status.

**-d** <param>  
param

<sup>1</sup> Displayed in the case of the fixed term license

<sup>2</sup> Displayed in the case of the license of trial version

- serialno** Deletes the license with the specified serial number.
- t** Deletes all the registered licenses of the trial version.
- a** Deletes all the registered licenses.
- q**  
Deletes licenses without displaying a warning message. This is used with -d option.
- distribute**  
License files are delivered to all servers in the cluster. Generally, it is not necessary to run the command with this option.
- reregister licensefile...**  
Reregisters the fixed term license. Generally, it is not necessary to run the command with this option.

Return Value

0	Normal termination
1	Cancel
2	Normal termination (with licenses not synchronized) * This means that license synchronization failed in the cluster at the time of license registration. For the actions to be taken, refer to "Troubleshooting for licensing" in Appendix A "Troubleshooting" in the "Installation and Configuration Guide".
3	Initialization error
5	Invalid option
8	Other internal error

Example of a command entry

- for registration
    - Registering the license interactively
- ```
# clplcns -i
```

Product Version/Product Version (Fixed Term)

Select a product division

```
Selection of License Version
 1. Product Version
 2. Trial Version
 e. Exit
Select License Version. [1, 2, or e (default:1)] ...
```

Enter a serial number

```
Enter serial number [ Ex. XXXXXXXX000000] .
```

Enter a license key

```
Enter license key
[ Ex. XXXXXXXX-XXXXXXX-XXXXXXX-XXXXXXX] ...
```

Trial Version

Select a product division

```
Selection of License Version
  1. Product Version
  2. Trial Version
  e. Exit
Select License Version. [1, 2, or e (default:1)] ...
```

Enter a user name

```
Enter user name [ 1 to 63byte ] .
```

Enter a license key

```
Enter license key
[Ex. XXXXX-XXXXXXXX-XXXXXXXX-XXXXXXXX] .
```

– Specify a license file

```
# clplcns -i /tmp/cpulcns.key
```

• for referring to the license

```
# clplcns -l
```

Product version

```
< EXPRESSCLUSTER X <PRODUCT> >
Seq... 1
  Key..... A1234567-B1234567-C1234567-D1234567
  Licensed Number of CPU... 2
  Status... valid
Seq... 2
  Serial No..... AAAAAAAAA000002
  Key..... E1234567-F1234567-G1234567-H1234567
  Licensed Number of Computers... 1
  Status... valid
```

Product version (fixed term)

```
< EXPRESSCLUSTER X <PRODUCT> >
Seq... 1
  Serial No..... AAAAAAAAA000001
  Key..... A1234567-B1234567-C1234567-D1234567
  Start date..... 2018/01/01
  End date..... 2018/01/31
  Status..... valid
Seq... 2
  Serial No..... AAAAAAAAA000002
  Key..... E1234567-F1234567-G1234567-H1234567
  Status..... inactive
```

Trial version

```
< EXPRESSCLUSTER X <TRIAL> >
Seq... 1
  Key..... A1234567-B1234567-C1234567-D1234567
  User name... NEC
```

(continues on next page)

(continued from previous page)

```
Start date..... 2018/01/01
End date..... 2018/02/28
Status..... valid
```

- for deleting the license

```
# clplcnsd -d AAAAAAAAA000001 -q
```

- for referring to deleting the license

```
# clplcnsd -d -t -q
```

- for deleting the license

```
# clplcnsd -d -a
```

Deletion confirmation

```
Are you sure to remove the license? [y/n] ...
```

## Notes

Run this command as the root user.

When you register a license, verify that the data transfer server is started up and a cluster has been generated for license synchronization.

When synchronizing the licenses, access the cluster servers in the order below, and use one of the paths that allowed successful access:

1. via the IP address on the interconnect LAN
2. via the IP address on the public LAN
3. via the IP address whose name was resolved by the server name in the cluster configuration data.

When you delete a license, only the license information on the server where this command was run is deleted. The license information on other servers is not deleted. To delete the license information in the entire cluster, run this command in all servers.

Furthermore, when you use -d option and -a option together, all the trial version licenses and product version licenses will be deleted. To delete only the trial license, also specify the -t option. If the licenses including the product license have been deleted, register the product license again.

When you refer to a license which includes multiple licenses, all included licenses information are displayed.

If one or more servers in the cluster are not working, it may take time to execute this command.

## Error Messages

| Message                                             | Cause/Solution                                                                                                                  |

## 8.13 Locking disk I/O (clproset command)

the clproset command modifies and displays I/O permission of the partition device.

### Command line

```
clproset -o [-d device_name | -r resource_name -t resource_type | -a | --lockout]
clproset -w [-d device_name | -r resource_name -t resource_type | -a | --lockout]
clproset -s [-d device_name | -r resource_name -t resource_type | -a | --lockout]
```

### Description

This command configures the partition device I/O permission of a shared disk to ReadOnly/ReadWrite possible.

This command displays the configured I/O permission status of the partition device.

### Option

- o**  
Sets the partition device I/O to ReadOnly. When ReadOnly is set to a partition device, you cannot write the data into the partition device.
- w**  
Sets the partition device I/O to ReadWrite possible. When ReadWrite is set to a partition device, you may read from and write the data into the partition device.
- s**  
Displays the I/O permission status of the partition device.
- d *device\_name***  
Specifies a partition device.
- r *resource\_name***  
Specifies a disk resource name.
- t *resource\_type***  
Specifies a group resource type. For the current EXPRESSCLUSTER version, always specify "disk" as group resource type.
- a**  
Runs this command against all disk resources.
- lockout**  
Runs this command against the device specified as a disk lock device.

### Return Value

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

### Notes

Run this command as the root user.

This command can only be used on shared disk resources. It cannot be used for mirror disk resources and hybrid disk resources.

Make sure to specify a group resource type when specifying a resource name.

**Example of command execution**

**Example 1:** When changing the I/O of disk resource name, disk1, to RW:

```
# clproset -w -r disk1 -t disk  
/dev/sdb5 : succeeded (disk1)
```

**Example 2:**When acquiring I/O information of all resources:

```
# clproset -s -a  
/dev/sdb5 : rw (disk)  
/dev/sdb6 : ro (raw)  
/dev/sdb7 : ro (lockout)
```

**Error Messages**

|----------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Log in as root.                                                                  | Log on as the root user.                                             |
| Invalid configuration file. Create valid cluster configuration data.             | Create valid cluster configuration data by using the Cluster WebUI.  |
| Invalid option.                                                                  | Specify a valid option.                                              |
| The -t option must be specified for the -r option.                               | Be sure to specify the -t option when using the -r option.           |
| Specify 'disk' or 'raw' to specify a group resource.                             | Specify "disk" or "raw" when specifying a group resource type.       |
| Invalid group resource name. Specify a valid group resource name in the cluster. | Specify a valid group resource name.                                 |
| Invalid device name.                                                             | Specify a valid device name.                                         |
| Command timeout.                                                                 | The OS may be heavily loaded. Check to see how heavily it is loaded. |
| Internal error. Check if memory or OS resources are sufficient.                  | Check to see if the memory or OS resource is sufficient.             |

---

**Note:**

Do not use this command for the purposes other than those mentioned in "Verifying operation" in the "Installation and Configuration Guide".

If you run this command while the cluster daemon is started, the file system may get corrupted.

---

## 8.14 Mirror-disk-related commands

### 8.14.1 Displaying the mirror status (clpmdstat command)

the clpmdstat command displays status related to mirroring and configuration information.

#### Command line

```
clpmdstat {--connect | -c} mirrordisk-alias  
clpmdstat {--mirror | -m} mirrordisk-alias  
clpmdstat {--active | -a} mirrordisk-alias  
clpmdstat {--detail | -d} mirrordisk-alias  
clpmdstat {--list | -l}  
clpmdstat {--perf | -p} [interval [count]] mirrordisk-alias
```

#### Description

This command displays the status related to mirroring.

This command displays mirror disk resources configuration information.

#### Option

**--connect, -c**  
Displays mirror disk connect status.

**--mirror, -m**  
Displays mirror disk resource status.

**--active, -a**  
Displays status of mirror disk activation.

**--detail, -d**  
Displays mirror disk resources configuration information.

**--list, -l**  
Displays mirror disk resources list.

**--perf**  
Displays statistical information on mirror disk resources.

#### Parameter

**mirrordisk-alias**  
Specifies a mirror disk resource name.

#### interval

Specifies the sampling interval for statistical information.  
If no value is specified, 60 (sec) is specified by default.  
You can specify a value from 1 to 9999.

#### count

Specifies the number of times statistical information is displayed.  
This parameter is used together with the *interval*. You can specify a value from 1 to 9999.

When *count* is omitted, statistical information is displayed indefinitely.

To stop displaying statistical information, press [Ctrl] + [C].

Both the default value of *interval*, 60, and of *count*, 1, are used if these parameters are omitted.

#### **Return value**

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

#### **Notes**

Run this command as the root user.

#### **Example display after running this command**

An example of the display after running this command is provided in the next topic.

#### **Error Messages**

| Message                                                                                                                                                        | Cause/Solution                                                                                                                                              |

Wait, and then execute the command again.<br>If this message displays again, make sure that mdagent is running normally.                                      |

## Display examples

- Mirror disk connect status display

When the --connect option is specified, the status of mirror disk connect is displayed.

```
Mirror Name : mdl

[Server : server1]

    192.168.0.1                : Using

[Server : server2]

    192.168.0.2                : Using
```

- Displaying the status of mirror disk resource

The status of specified mirror disk resource is displayed by specifying the --mirror option. There are three types of display depending on the status of mirror disk resource:

- When the status of mirror disk resource is Normal:

|                       |         |         |
|-----------------------|---------|---------|
| Mirror Status: Normal |         |         |
| mdl                   | server1 | server2 |
| -----                 |         |         |
| Mirror Color          | GREEN   | GREEN   |

| Percent         | Percentage of how much data is already recovered                                                                                                                                                                                                                                                                                                                                                                                                                                                        |        |             |           |                           |            |                 |            |                                      |         |                    |
| Used Time       | Elapsed time since recovering has started                                                                                                                                                                                                                                                                                                                                                                                                                                                               |        |             |           |                           |            |                 |            |                                      |         |                    |
| Remain Time     | Estimated time to complete recovering the remaining data. It is estimated by the speed of already recovered data. The time may be different depending on server load.                                                                                                                                                                                                                                                                                                                                   |        |             |           |                           |            |                 |            |                                      |         |                    |
| Iteration Times | The current repeat counts and the setting value of the mirror recovery.                                                                                                                                                                                                                                                                                                                                                                                                                                 |        |             |           |                           |            |                 |            |                                      |         |                    |

- Displaying active status of mirror disk resource

Active status of the specified mirror disk resource is displayed when the --active option is specified:

|               |         |          |
|---------------|---------|----------|
| mdl           | server1 | server2  |
| -----         |         |          |
| Active Status | Active  | Inactive |

Status of mirror partition device

| Active Status | Description |
|---------------|-------------|
| Active        | Active      |
| Inactive      | Not active  |
| --            | Unknown     |

- Displaying mirror disk resource information

Configuration information of the specified mirror disk resource is displayed when the --detail option is specified:

|                    |             |
|--------------------|-------------|
| Mirror Name        | : mdl       |
| Sync Switch        | : On        |
| Sync Mode          | : Sync      |
| Diff Recovery      | : --        |
| Compress           | :           |
| Sync Data          | : Off       |
| Recovery Data      | : On        |
| [Server : server1] |             |
| NMP/Disk Size (MB) | : 2447/2447 |

- Displaying the list of mirror disk resources

The list of mirror disk resources is displayed when the --list option is specified:

```

[Replicator Option]

server1 : Installed
server2 : Installed
server3 : Installed

[Servers Which Can Be Started]
<md1>
  server1
  server3

<md2>
  server2
  server3

```

Explanation of each item

| Item                         | Description                                           |
|------------------------------|-------------------------------------------------------|
| Replicator Option            | License status of the Replicator                      |
| Servers Which Can Be Started | Servers which can be started of mirror disk resources |

- Displaying statistical information

Performance figures for the mirroring function are displayed when the `--perf` option is specified:

|                    |      |                   |      |                   |      |                   |      |                |      |

Table 8.41 – continued from previous page

| Item           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SyncTime (Avg) | <p>Time required for synchronizing one mirror synchronization data item. The output value indicates the average time per communication. The unit is seconds/communication.</p> <p>The time required for synchronizing mirror synchronization data which cannot be synchronized due to disabled communication or another cause (which causes a mirror break) is not included.</p> <p>The output value indicates the average time required for communication during each sampling interval.</p> |
| SyncDiff (Max) | <p>Amount of mirror synchronization data which has not been synchronized with that on a remote server. The output value indicates the maximum value during each sampling interval. The unit is MB.</p> <p>The amount of mirror synchronization data which cannot be synchronized due to disabled communication or another cause (which causes a mirror break) is not included.</p>                                                                                                            |
| SyncDiff (Cur) | <p>Amount of mirror synchronization data which has not been synchronized with that on a remote server. The output value indicates the latest amount at collection. The unit is MB.</p> <p>The amount of mirror synchronization data which cannot be synchronized due to disabled communication or another cause (which causes a mirror break) is not included.</p>                                                                                                                            |

- The clpmdstat command displays statistical information to two decimal places. Actually collected data is converted to an appropriate unit and truncated to two decimal places when displayed. The following rules are used for conversion:  
1 KB = 1024 bytes, 1 MB = 1048576 bytes
- When the result of truncating data is 0, "0.00" is displayed. When not that result, but the actual data is 0, "None" is displayed.
- The output value becomes information in the server that executed the command. Valid values are output only in the active server for Write (Total), Write (Avg), Read (Total), Read (Avg), SyncTime (Max), SyncTime (Avg), SyncDiff (Max), and SyncDiff (Cur). The status of these values is either hold or "none" in a standby server. Valid values are output in both active and standby servers for Send (Total) and Send (Avg).

### 8.14.2 Operating mirror disk resource (clpmdctrl command)

the clpmdctrl command operates mirror disk resources.

#### Command line

```
clpmdctrl [--active | -a] mirrordisk-alias
clpmdctrl [--active | -a] -nomount mirrordisk-alias
clpmdctrl [--active | -a] -force [-ro] mirrordisk-alias
clpmdctrl [--active | -a] -force -nomount mirrordisk-alias
```

```
clpmdctl {--deactive | -d} mirrordisk-alias  
clpmdctl {--break | -b} mirrordisk-alias  
clpmdctl {--recovery | -r} mirrordisk-alias  
clpmdctl {--force | -f} [-v] recovery-source-servername mirrordisk-alias  
clpmdctl {--force | -f} mirrordisk-alias  
clpmdctl {--cancel | -c} mirrordisk-alias  
clpmdctl {--rwait | -w} [-timeout time [-rcancel]] mirrordisk-alias  
clpmdctl --getreq  
clpmdctl --setreq request-count  
clpmdctl --sync [mirrordisk-alias]  
clpmdctl --nosync [mirrordisk-alias]  
clpmdctl {--compress | -p} [mirrordisk-alias]  
clpmdctl {--nocompress | -n} [mirrordisk-alias]  
clpmdctl {--mdcswitch | -s} [mdc-priority] mirrordisk-alias  
clpmdctl {--resize | -z} [-force] partition-size mirrordisk-alias  
clpmdctl --updatekey mirrordisk-alias
```

---

**Important:**

After releasing the access limitation to the mirror disk partition by --active option, make sure to put the access limitation again by --deactive option.

Additionally, do not use --deactive option while the resource is in active status.

If the resource in the active status is started or stopped, the file system may be corrupted.

---

---

**Note:** When you extend the data partition of the mirror disk resource by using --resize option, extend both servers by following "Maintenance Guide" -> "The system maintenance information" -> "Changing offset or size of a partition on mirror disk resource".

---

---

**Note:** When you extend the data partition of the mirror disk resource by using --resize option, the data partition must be configured with LVM and the amount of unused PE (physical extent) of the volume group must be sufficient.

---

---

**Note:** In updating an encryption key with the --updatekey option, follow the procedures specified in "Maintenance Guide" -> "The system maintenance information" -> "Updating data encryption key file of mirror/hybrid disk resources".

---

**Description**

This command activates, deactivates or forcibly activates mirror disk resource and recovers or forcibly recovers mirror.

This command disconnects a mirror disk.

This command performs mirror recovery, forced mirror recovery, cancellation of mirror recovery, and waiting for the completion of mirror recovery.

This command displays and/or modifies the settings of maximum number of request queues.

This command switches the synchronization status of the mirror data.

This command is used to set whether mirror data is to be compressed.

This command switches the communication path (mirror disk connect) to be used.

This command extends the data partition size.

#### Option

##### **--active, -a**

Activates the mirror disk resource on the local server.

If the status of mirror disk resource is normal, mirroring is performed.

If the status of mirror disk resource is not normal, mirroring will not be performed.

##### **-force(--active, -a)**

Forcibly activates a mirror disk resource.

This command can be run on a server where mirroring is stopped.

This option is used with the --active option.

##### **-nomount**

It allows access to mirror partition device without mounting the file system.

This option is used with the --active option.

This option has no meaning if none is specified for the file system.

##### **-ro**

Forcibly activates a mirror disk resource in ReadOnly mode.

This option is used with the --active -force options.

##### **--deactive, -d**

Deactivates the activated mirror disk resource on the local server.

##### **--break, -b**

Disconnects the mirror disk resources forcibly specified with *mirrordisk-alias* on the server where the command is run.

The status of mirror disk resource on the server where the command is run becomes an error. The status on the server where the command is not run does not change.

When a mirror is recovered, disconnection is canceled.

Mirror data is not synchronized even when any data is written to a mirror disk.

Auto mirror recovery is not automatically started until reboot is performed or disconnection is canceled after completion of mirror recovery.

##### **--recovery, -r**

Performs either full mirror recovery or differential mirror recovery for the specified mirror disk resource.

Whether to perform full or differential mirror recovery is determined automatically.

##### **--force, -f**

Forcefully performs mirror recovery for the specified mirror disk resource.

*If only `mirrordisk-alias` is specified, the status of mirror disk where the command is run becomes normal forcibly. Mirror resynchronization is not performed.*

*If `recovery-source-servername` and `mirrordisk-alias` are specified, full mirror recovery is performed using `recovery-source-servername` as source data.*

*The status of mirror disk becomes normal when a full mirror recovery completes.*

**-v**

Forcefully performs mirror recovery without an analysis of the file system.

**--cancel, -c**

Cancels mirror recovery.

When **Auto Mirror Recovery** is selected and a mirror disk monitor resource is operating, mirror recovery is automatically resumed a while after it is canceled. In this case, suspend the mirror disk monitor resource by using the Cluster WebUI or `clpmonctrl` command, then run the command for canceling mirror recovery.

**--rwait, -w**

Waits for the completion of the mirror recovery of the specified mirror disk resource.

**-timeout**

Specifies the timeout period of mirror recovery completion (second). This option can be omitted.

When this option is omitted, timeout is not executed and waits for the completion of mirror recovery.

**-rcancel**

Cancels mirror recovery when the timeout of waiting of mirror recovery completion occurred. This option can be set when `-timeout` option is set.

When this option is omitted, the mirror recovery continues even after the timeout occurrence.

**--getreq**

Displays the current maximum number of request queues.

**--setreq**

Configures the maximum number of request queues.

When the server shuts down, what you have configured here returns to the value set in the cluster configuration data. Use the Cluster WebUI if you want to modify the cluster configuration data. For details, see "[Cluster properties](#)" "[Mirror driver tab ~ For Replicator/Replicator DR ~](#)" in "[2. Parameter details](#)" in this guide.

The command is only effective on the server that runs the command.

**--sync**

This option switches the operation to the mirror synchronization.

When the mirror disk resource name is not specified, the operation is switched to synchronizing the mirror data to all mirror resources.

**--nosync**

This option switched the operation to the one that does not synchronize the mirror data.

When the mirror disk resource name is not specified, the operation is switched to not performing the synchronization of the mirror data to all mirror resources.

However, the data updated to a disk during a mirror recovery is synchronized to a standby server. If auto mirror recovery is set to ON and the mirror disk monitor resource is operating, automatic mirror recovery will operate.

Even after the completion of mirror recovery, the operation will still not synchronize. To cancel this, execute the command with the `--sync` option specified.

When the server is shut down, the state will return to the synchronization operation that is set in the cluster configuration information. To change the cluster configuration information, use the Cluster WebUI. For details, see "Mirror tab" in "Mirror disk resource tuning properties" in "[Details tab](#)" in "Understanding mirror disk resources" in "[3. Group resource details](#)" in this guide.

#### **`--compress, -p`**

Temporarily switches on the compression mode of mirror transfer data.

If the synchronous mode of mirror data is "Synchronous", only the recovery transfer data is compressed.

If the synchronous mode of mirror data is "Asynchronous", both the asynchronous transfer data and the recovery transfer data are compressed.

When the mirror disk resource name is not specified, the operation is performed to all mirror disk resources.

#### **`--nocompress, -n`**

Temporarily switches off the compression mode of mirror transfer data.

When the mirror disk resource name is not specified, the operation is performed to all mirror disk resources.

#### **`--mdcswitch, -s`**

Switches the mirror connection to another mdc that has the specified priority.

If the priority is not specified, the mirror connection is switched to the mdc that has the next highest priority after the current mdc. If the mirror connection is connected to the mdc that has the lowest priority, it is switched to the one that has the highest priority.

If the mirror connection has already been switched to the specified mdc, the command terminates normally without performing any processing.

If the specified mdc does not exist, an error occurs.

#### **`--resize, -z`**

Extends the data partition size of mirror disk resource.

The extension is available only when the status of mirror disk resource is normal.

#### **`-force(--resize,-z)`**

Use with the `--resize` option.

Forcibly executes the extension regardless of the state of the mirror disk resource.

If this option is used, full copy of the mirror disk will be executed for the next time.

In addition, even if this option is used, the extension is unavailable during the mirror recovery.

#### **`--updatekey`**

Updates the encryption key without stopping the resource.

The execution of this option, after completing the update of the encryption key files for both of the servers, updates the key for the encryption.

At this time, mirroring in progress is suspended. As required, execute mirror recovery after the execution.

#### Parameter

##### **recovery-source-servername**

Specifies a server name of the copy source.

##### **mirrordisk-alias**

Specifies a mirror disk resource name.

##### **request-count**

Specifies a maximum number of request queues.

You can specify a number from 2048 through 65535.

##### **time**

Specifies the timeout period of mirror recovery completion (second).

##### **mdc-priority**

Specifies the priority of mdc.

This is not the priority number of mdc in whole cluster, but the priority number (1 or 2) of mdc used by the mirror disk resource.

##### **partition-size**

Specifies the new size of data partition. For the unit, use the following symbol. If "500G" is specified, the size is extended to 500 gibibytes. If the symbol of the unit is not used, the amount is regarded as in byte.

- K (Kibi byte)
- M (Mibi byte)
- G (Gibi byte)
- T (Tebi byte)

#### Return Value

|             |                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Success                                                                                                                                                                                                     |
| 255<br>(-1) | Failure                                                                                                                                                                                                     |
| 254<br>(-2) | Target mirror disk is not configuring mirror, or the mirror configuring failed on the process. (Only when --rwait option is specified, including the case when mirror recovery is interrupted by -rcancel.) |
| 253<br>(-3) | Timeout of mirror recovery of target mirror disk occurs (Only when --rwait -timeout option is specified)                                                                                                    |

#### Remarks

*request-count*, which is displayed by specifying the --getreq option, is the same as "Max. Number of Request Queues" which is displayed by using the clpstat command.

# clpstat --cl --detail

This command returns control when the specified processing starts. Run the clpmdstat command to check the processing status.

#### Notes

Run this command as the root user.

When performing mirror recovery again after mirror recovery failed, specify the same server you used last time for mirror recovery as a copy source.

To resume the forced mirror recovery that was suspended by selecting **Cancel**, use this command for forced mirror recovery.

In a cluster with more than three nodes, if the server where the command is run is not included in a startup server of a group including mirror disk resources, this command results in error. Do not run this command if the server is not included in a startup server of a group.

If, during mirror synchronization, mirror synchronization is interrupted with either the `--break (-b)` or `--nosync` option or if, during mirror recovery, mirror recovery is interrupted, the file system and application data may prove to be abnormal even if the mirror disk to be synchronized is made accessible by performing forced activation or forced mirror recovery. For details, see "Mirror data reference at the synchronization destination if mirror synchronization is interrupted" in "Notes and Restrictions" in the "Getting Started Guide".

#### Example of command execution

**Example 1:** When activating the mirror disk resource md1:

```
# clpmdctrl --active md1
<md1@server1>: active successfully
```

**Example 2:** When deactivating the mirror disk resource md1:

```
# clpmdctrl --deactive md1
<md1@server1>: deactive successfully
```

**Example 3:** When disconnecting the mirror disk resource md1:

```
# clpmdctrl --break md1
md1: isolate successfully
```

**Example 4:** When the status of both servers is error, and you need to recover the operation which uses the resource md1 as soon as possible:

```
# clpmdctrl --force md1
The data of mirror disk in local server maybe is not latest.
Do you still want to continue? (Y/N)
md1: Force recovery successful.
```

```
# clpgrp -s failover1
Command succeeded.
```

When **Auto Mirror Recovery** is selected, mirror recovery is performed at this timing. When **Auto Mirror Recovery** is cleared, run the following command.

```
# clpmdctrl --recovery md1
```

**Example 5:** When mirror recovering the mirror disk resource md1:

```
# clpmdctrl --recovery md1
```

**Example 6:** When setting the maximum number of request queues to 2048:

```
# clpmdctrl --setreq 2048
current I/O request count <2048>
```

**Example 7:** When configure the setting that does not perform the data synchronization to the mirror disk resource md1:

```
# clpmdctrl --nosync md1
```

#### Error Messages

| Error: Initial mirror configuration of mirror disk of the other server is necessary. Specify the local server as the one that is copied from by using the <code>clpmdctrl --force</code> command to configure an initial mirror.                                                                                                                                       | Initial mirror construction is necessary for the mirror disk of the remote server. Specify the local server as a copy source and construct initial mirror using " <code>clpmdctrl --force</code> ."                                                                                                                                                                                                                                                                                                           |
| Error: Mirror flag error. Use " <code>clpmdinit</code> " to construct the mirror. The status of cluster partition of the mirror disk resource is abnormal. When the server with the error has the latest data, backup the data, initialize the cluster partition, and replace the same disk by using the same disk. If the error persists, change the disk to new one. | The cluster partition of the mirror disk resource has a problem. When the server with error has the latest data, back up the data, initialize the cluster partition according to Chapter 8 "Verifying Operation" in the Installation and Configuration Guide, and follow the same way as described in "How to replace a mirror disk with a new one" in Chapter 1, "The system maintenance information" in the maintenance guide, using the same disk. If this occurs again, replace the disk with a new disk. |
| Error: Both local and remote mirrors are active. Shut down the cluster and execute forced mirror recovery after rebooting the server.                                                                                                                                                                                                                                  | Both systems are active. Shut down the cluster and perform forced mirror recovery after reactivating the server.                                                                                                                                                                                                                                                                                                                                                                                              |
| Error: Mirror Agent is not running. Check if the Mirror Agent is active.                                                                                                                                                                                                                                                                                               | The Mirror Agent is not started up. Check to see if the Mirror Agent is running.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Error: System calls error. Failed to run the system command when active and/or inactive. Check if the search path is set to an environment variables.                                                                                                                                                                                                                  | Running the system command when active/inactive has failed. Check to see if a search path is set as an environmental variable.                                                                                                                                                                                                                                                                                                                                                                                |

| Failed to enable auto recovery. It is necessary to recover the mirror manually, in order to resume mirroring. | The encryption key has been updated. The mirroring, however, is suspended. Mirror recovery must be performed manually.                                                  |

### 8.14.3 Initializing mirror disks (clpmdinit command)

the clpmdinit initializes a mirror disk.

#### Command line

```
clpmdinit {--create | -c} normal [mirrordisk-alias]  
clpmdinit {--create | -c} quick [mirrordisk-alias]  
clpmdinit {--create | -c} force [mirrordisk-alias]
```

---

**Important:** Generally you do not need to run this command when constructing or operating a cluster. You should exercise caution when you use this command because the partition used for the data will be initialized.

---

#### Description

This command initializes the cluster partition of a mirror disk resource.

This command creates a file system on the data partition of a mirror disk resource (except when none is specified for the file system).

#### Option

```
{--create, -c} <mode>  
mode  
  
normal
```

Initializes a cluster partition and creates a file system of the data partition, if necessary.<sup>5</sup>  
The necessity is determined by the magic number set by EXPRESSCLUSTER on the cluster partition.

Generally, it is not necessary to run the command with this option.

**quick**

Initializes the cluster partition, if necessary.

Whether or not it is necessary to initialize the cluster partition is determined by the magic number set by EXPRESSCLUSTER on the cluster partition.

Generally, it is not necessary to run the command with this option.

**force**

Forcefully initializes the cluster partition and creates a file system of the data partition.<sup>5</sup>

This option is used when using the disk that was once used as a mirror disk of EXPRESSCLUSTER again.

**Parameter****mirrordisk-alias**

Specifies a mirror disk resource name.

If this parameter is not specified, the process is performed on all mirror disk resources.

**Return Value**

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

**Notes**

You should exercise caution when you run this command because the mirror disk will be initialized.  
Run this command as the root user.

Do not run other commands, until this command is returned.

When running this command, make sure that the Mirror Agent in all servers in the cluster is stopped.

- To check the Mirror Agent is stopped on all servers, run the following command:

```
# ps -e | grep clpmdagent
```

In a cluster with more than three nodes, if the server where the command is run is not included in a startup server of a group including mirror disk resources, this command results in error. Do not run this command if the server is not included in a startup server of a group.

**Example of command execution**

**Example 1:** When forcefully initializing the cluster partition because the disk to be used for the mirror disk resource mdl was once used as a mirror disk of EXPRESSCLUSTER:

```
# clpmdinit --create force mdl  
mirror info will be set as default  
the main handle on initializing mirror disk <mdl> success  
initializing mirror disk complete
```

<sup>5</sup> Unless "Execute initial mkfs" is selected in the cluster configuration data, the file system will not be created.

## Error Messages

#### 8.14.4 Preparing for backup to a disk image (clpbackup.sh command)

Allows a partition to be mirrored to be backed up to its disk image.

##### Command line

```
clpbackup.sh --pre
clpbackup.sh --pre --only-shutdown
clpbackup.sh --post
clpbackup.sh --post --only-reboot
```

`clpbackup.sh --help`

### **Description**

Execute this command when backing up the disk for mirroring on a server (i.e., the cluster partition and the data partition) to its disk image, or the system disk on the server containing those to its disk image.

Execute this command as follows:

1. Run the `clpbackup.sh --pre` command, which places the mirror into a backup mode and the server shuts down.
2. Back up a disk to its disk image.
3. Run the `clpbackup.sh --post` command, which returns the mirror to a normal mode and the server restarts.
4. After the server is restarted, perform mirror recovery to synchronize differences generated during the backup.

In restoring from the disk image backed up, use the `clprestore.sh` command.

For the procedure of backing up disks to their disk images with this command, see "Maintenance Guide" -> "The system maintenance information" -> "How to back up a mirror/hybrid disk to its disk image".

### **Option**

#### **--pre**

Use this option for backing up partitions to be mirrored fully to its disk image, or backing up a system disk on a server containing those to its disk image.

Execute the command with this option immediately before the backup.

Executing the command with this option places all the cluster partitions and the data partitions (i.e., the partitions to be mirrored) into a backup mode and the server shuts down.

After shutting down and then starting the server, the EXPRESSCLUSTER service is not automatically started at the next startup of the server.

The status of the mirror in a backup mode is not of the latest (status: red) and the mirror recovery by full-copy needs to be performed. Automatic mirror recovery is not performed.

#### **--post**

Executing the command with this option clears the backup mode, which was set by the `--pre` option, to return to a normal mode, and the server restarts.

After the completion of the restart, the EXPRESSCLUSTER service automatically starts.

Execute the command with this option after the completion of backup to the disk image.

#### **--only-shutdown**

Use this option if there are multiple servers in the server group with hybrid disk resources.

After the completion of executing the `clpbackup.sh --pre` command on the first server in the server group, execute the `clpbackup.sh --pre --only-shutdown` command on the remaining servers in the server group.

### **--only-reboot**

Use this option if there are multiple servers in the server group with hybrid disk resources.

After the completion of executing the `clpbackup.sh --post` command on the first server in the server group, execute the `clpbackup.sh --post --only-reboot` command on the remaining servers in the server group.

### **--help**

Displays the usage.

### **Return Value**

|   |         |
|---|---------|
| 0 | Success |
| 1 | Failure |

### **Remarks**

In a backup mode, the status of the mirror is not of the latest (status: red) and the automatic mirror recovery is not performed. Not differential copy but full copy is executed at the mirror recovery.

This command applies not to the backup and restoration of files, but to those of disk images.

The procedure of using this command is different from that for backing up files from activated mirror disks/hybrid disks or backing up files from standby mirror disks/hybrid disks by canceling the access restriction.

### **Notes**

Run this command as the root user.

The execution of this command applies all the mirror disk resources and hybrid disk resources on the server.

Back up/restore both of the cluster partition and the data partition.

Executing this command causes the server to shut down or to restart.

This function does not apply to a cluster environment including a server with a version earlier than 4.3 of EXPRESSCLUSTER installed.

### **Error Message**

| Message                     | Cause/Solution                                                                                               |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| Invalid option.             | Specify a valid option.                                                                                      |

| Command failed.             | This command failed.<br>Check for any error message displayed immediately before this error message appears. |

### **Example of command execution**

Example 1: Causing mirror disk resources and hybrid disk resources to enter a backup mode prior to the execution of the backup:

```
# clpbackup.sh --pre
clpbackup.sh : Beginning backup-mode.
All backup flags have set to <ON>.
clpbackup.sh : Changing the setting of cluster services to Manual Startup.
clpbackup.sh : Shutting down...
Command succeeded.
clpbackup.sh : Command succeeded.
Example 2: Ending the backup mode after the completion of the backup:
# clpbackup.sh --post
clpbackup.sh : Starting Mirror Agent.
Command succeeded.
clpbackup.sh : Ending backup-mode.
All backup flags have set to <OFF>.
clpbackup.sh : Changing the setting of cluster services to Auto Startup.
clpbackup.sh : Stopping Mirror Agent.
Command succeeded.
clpbackup.sh : Rebooting...
Reboot server1 : Command succeeded.
clpbackup.sh : Command succeeded.
```

### **8.14.5 Perform the processing after restoring from a disk image (clprestore.sh command)**

Allows a restored mirror disk image to be available.

#### **Command line**

```
clprestore.sh --pre
clprestore.sh --pre --only-shutdown
clprestore.sh --post
clprestore.sh --post --only-reboot
clprestore.sh --post --skip-copy
clprestore.sh --help
```

#### **Description**

Execute this command in restoring the cluster partition and the data partition from its disk image, or the system disk on the server containing those from its disk image.

Execute this command as follows:

1. Run the `clprestore.sh --pre` command, which disables the automatic startup of the EXPRESSCLUSTER service and the server shuts down.
2. Restore from the disk image.
3. Check the path of the cluster partition and that of the data partition. If any of the paths differs from before, use Cluster WebUI to change the setting of the corresponding mirror disk resource/hybrid disk resource.
4. Run the `clprestore.sh --post` command, which enables the automatic startup of the EXPRESSCLUSTER service and the server restarts.
5. After the restart of the server, perform the mirror recovery in Cluster WebUI or with the command. The data is fully copied and the mirror becomes synchronized. (Full copy is not required when

--skip-copy is specified.)

For backing up the disk image, run the clpbackup.sh command.

For the procedure of restoring from disk images with this command, see "Maintenance Guide" -> "The system maintenance information" -> "How to restore the mirror/hybrid disk from the disk image".

## Option

### --pre

Running the command with this option disables the automatic startup of the EXPRESSCLUSTER service and the server shuts down.

The EXPRESSCLUSTER service is therefore not automatically started at the next startup of the server.

Before restoring from the disk image, run this command at the time of shutting down the server.

When not starting the server, or restoring the system disk as well, this command does not need to be executed before the restoration.

### --post

Running the command with this option enables the automatic startup of the EXPRESSCLUSTER service and the server restarts.

Execute this command after restoring from the disk image.

### --skip-copy

Specify this option with the --post option.

This option can be specified only when the same disk image is restored to both of the active server and the standby server.

Full copy is not necessary at the time of mirror recovery.

In running the command with this option, **Execute the initial mirror construction** needs to be disabled in advance in the settings of mirror disk resources and hybrid disk resources.

### --only-shutdown

Use this option if there are multiple servers in the server group with hybrid disk resources.

After the completion of executing the clprestore.sh --pre command on the first server in the server group, execute the clprestore.sh --pre --only-shutdown command on the remaining servers in the server group.

This option can be omitted.

### --only-reboot

Use this option if there are multiple servers in the server group with hybrid disk resources.

After the completion of executing the clprestore.sh --post command or the clprestore.sh --post --skip-copy command on the first server in the server group, execute the clprestore.sh --post --only-reboot command on the remaining servers in the server group.

This option can be omitted.

**--help**

Displays the usage.

#### Return Value

|   |         |
|---|---------|
| 0 | Success |
| 1 | Failure |

#### Remarks

This command applies not to the backup and restoration of files, but to those of disk images.

The procedure of using this command is different from that for backing up files from activated mirror disks/hybrid disks or backing up files from standby mirror disks/hybrid disks by canceling the access restriction.

#### Notes

Run this command as the root user.

The execution of this command applies all the mirror disk resources and hybrid disk resources on the server.

Back up/restore both of the cluster partition and the data partition.

Executing this command causes the server to shut down or to restart.

This function does not apply to a cluster environment including a server with a version earlier than 4.3 of EXPRESSCLUSTER installed.

#### Error Message

| Set "Initial Mirror Construction" parameter and "Initial mkfs" parameter of md/hd resource to off by using Cluster WebUI. | In specifying the --skip-copy option, <b>Execute the initial mirror construction</b> must be disabled in the settings of the md/hd resources.<br>Before running the command, disable <b>Execute the initial mirror construction</b> in the config mode of Cluster WebUI. |
| Log directory is not found.                                                                                               | Installation is not correctly performed or you do not have the administrator privilege.                                                                                                                                                                                  |
| Command failed.                                                                                                           | This command failed.<br>Check for any error message displayed immediately before this error message appears.                                                                                                                                                             |

#### Example of command execution

Example 1: Shutting down before the restoration:

```
# clprestore.sh --pre
```

```
clprestore.sh : Changing the setting of cluster services to Manual.
```

→Startup.

clprestore.sh : Shutting down...

Command succeeded.

clprestore.sh : Command succeeded.

**Example 2: Starting a cluster after the restoration is performed:**

```
# clprestore.sh --post
```

clprestore.sh : Changing the setting of cluster services to Auto Startup.

clprestore.sh : Rebooting...

Reboot server1 : Command succeeded.

clprestore.sh : Command succeeded.

**Example 3: Starting a cluster after the same image is restored to both of the servers: (\*)**

```
# clprestore.sh --post --skip-copy
```

Mirror info will be set as default.

The main handle on initializing mirror disk <mdl> success.

Initializing mirror disk complete.

clprestore.sh : Changing the setting of cluster services to Auto Startup.

clprestore.sh : Rebooting...

Reboot server1 : Command succeeded.

clprestore.sh : Command succeeded.

(\* In the course of the process, a message of mirror disk initialization appears. The data partition is however not initialized.)

## 8.15 Hybrid-disk-related commands

### 8.15.1 Displaying the hybrid disk status (clphdstat command)

the clphdstat command displays status related to mirroring and configuration information.

#### Command line

```
clphdstat {--connect | -c} hybriddisk-alias  
clphdstat {--mirror | -m} hybriddisk-alias  
clphdstat {--active | -a} hybriddisk-alias  
clphdstat {--detail | -d} hybriddisk-alias  
clphdstat {--list | -l}  
clphdstat {--perf | -p} [interval [count]] hybriddisk-alias
```

#### Description

This command displays the status related to mirroring of hybrid disk.

This command displays hybrid disk resources configuration information.

#### Option

**--connect, -c**  
Displays the status of mirror connect used by hybrid disk resource.

**--mirror, -m**  
Displays the mirroring status of hybrid disk resource.

**--active, -a**  
Displays status of hybrid disk resource activation.

**--detail, -d**  
Displays hybrid disk resources configuration information.

**--list, -l**  
Displays hybrid disk resources list.

**--perf**  
Displays statistical information on hybrid disk resources.

#### Parameter

**hybriddisk-alias**  
Specifies a hybrid disk resource name.

#### interval

Specifies the sampling interval for statistical information. If no value is specified, 60 (sec) is specified by default.

You can specify a value from 1 to 9999.

#### count

Specifies the number of times statistical information is displayed. This parameter is used together with the *interval*. You can specify a value from 1 to 9999.

When *count* is omitted, statistical information displays indefinitely. To stop displaying statistical information, press [Ctrl] + [C].

Both the default value of *interval*, 60, and of *count*, 1, are used if these parameters are omitted.

#### Return value

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

#### Notes

Run this command as the root user.

If there is no current server in the server group, the server in which a mirror agent is working normally becomes the current server.

The server having the highest priority in server priority in **Server Group Properties** is selected.

#### Example display after running this command

An example of the display after running this command is provided in the next topic.

#### Error Messages

## Display examples

- Hybrid disk connect status display

When the --connect option is specified, the status of mirror connect that is used by hybrid disk resource is displayed.

```
Hybrid Disk Name : hdl

[Server : server1]
  192.168.0.1           : Using

[Server : server2]
  192.168.0.2           : Using
```

Explanation of each item

| Item        | Description        |
|-------------|--------------------|
| Server Name | Name of the server |

- Displaying the status of mirroring of hybrid disk resource

The status of mirroring of the specified hybrid disk resource is displayed by specifying the --mirror option.

- When the status of mirror disk resource is Normal:

|                       |         |         |
|-----------------------|---------|---------|
| Mirror Status: Normal |         |         |

Explanation of each item

See "Explanation of each item" of "*Displaying the mirror status (clpmdstat command)*."

- Displaying active status of hybrid disk resource

Active status of the specified hybrid disk resource is displayed when the --active option is specified:

<sup>6</sup> See "Explanation of each item" in "When the status of mirror disk resource is Normal:"

|               |         |          |
|---------------|---------|----------|
| hd1           | server1 | server2  |
| -----         |         |          |
| Active Status | Active  | Inactive |

Status of mirror partition device

See "Status of mirror partition device" of "*Displaying the mirror status (clpmdstat command).*"

- Displaying hybrid disk resource information

Configuration information of the specified hybrid disk resource is displayed when the --detail option is specified:

```
Hybrid Disk Name      : hd1
Sync Switch          : On
Sync Mode             : Sync
Diff Recovery         : Disable
Compress              :
  Sync Data           : Off
  Recovery Data       : Off

[Server : server1]
NMP/Disk Size(MB)    : 2447/2447
DP Device            : /dev/sdb2
CP Device            : /dev/sdb1

[Server : server2]
NMP/Disk Size(MB)    : 2447/2447
DP Device            : /dev/sdb2
CP Device            : /dev/sdb1
```

Explanation of each item

| Item              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| Hybrid Name       | Hybrid disk resource name                                                                   |
| Sync Switch       | Perform data synchronization                                                                |
| Sync Mode         | Synchronization Mode                                                                        |
| Server Name       | Current server name                                                                         |
| NMP/Disk Size(MB) | NMP: the smaller size of data partition of servers<br>Disk Size: actual data partition size |
| DP Device         | Data partition device name                                                                  |
| CP Device         | Cluster partition device name                                                               |

- Displaying the list of hybrid disk resources

The list of hybrid disk resources is displayed when the --list option is specified:

```
[HybridDisk Option]
server1 : Installed
server2 : Installed
server3 : Installed

[Servers Which Can Be Started]
<hd1>
[ServerGroup0 : server_group1]
 *server1
  server2
[ServerGroup1 : server_group2]
```

(continues on next page)

(continued from previous page)

```

*server3
<hd2>
[ServerGroup0 : server_group1]
  server1
*server2
[ServerGroup1 : server_group2]
  *server3

```

Explanation of each item

See "Displaying statistical information" of "*Displaying the mirror status (clpmdstat command)*"

## 8.15.2 Operating hybrid disk resource (clphdctrl command)

the clphdctrl command operates hybrid disk resources.

### Command line

```

clphdctrl [--active | -a] hybriddisk-alias
clphdctrl [--active | -a] -nomount hybriddisk-alias
clphdctrl [--active | -a] -force [-ro] hybriddisk-alias
clphdctrl [--active | -a] -force -nomount hybriddisk-alias
clphdctrl [--deactive | -d] hybriddisk-alias
clphdctrl [--break | -b] hybriddisk-alias
clphdctrl [--force | -f] [-v] recovery-source-servername hybriddisk-alias
clphdctrl [--force | -f] hybriddisk-alias
clphdctrl [--recovery | -r] hybriddisk-alias
clphdctrl [--cancel | -c] hybriddisk-alias
clphdctrl [--rwait | -w] [-timeout time [-rcancel]] hybriddisk-alias
clphdctrl --getreq
clphdctrl --setreq request-count
clphdctrl --sync [hybriddisk-alias]
clphdctrl --nosync [hybriddisk-alias]
clphdctrl --setcur hybriddisk-alias
clphdctrl [--compress | -p] [hybriddisk-alias]
clphdctrl [--nocompress | -n] [hybriddisk-alias]
clphdctrl [--mdcswitch | -s] [mdc-priority] hybriddisk-alias
clphdctrl [--resize | -z] [-force] partition-size hybriddisk-alias
clphdctrl --updatekey hybriddisk-alias

```

### Important:

After releasing the access limitation to the mirror disk partition by `--active` option, make sure to put the access limitation again by `--deactive` option.

Additionally, do not use `--deactive` option while the resource is in active status.

If the resource in the active status is started or stopped, the file system may be corrupted.

---

---

**Note:** In updating an encryption key with the `--updatekey` option, follow the procedures specified in "Maintenance Guide" -> "The system maintenance information" -> "Updating data encryption key file of mirror/hybrid disk resources".

---

### **Description**

This command activates, deactivates or forcibly activates hybrid disk resource and recovers or forcibly recovers mirror.

This command disconnects a hybrid disk.

This command performs mirror recovery, forced mirror recovery, cancellation of mirror recovery, and waiting for the completion of mirror recovery.

This command displays and/or modifies the settings of maximum number of request queues.

This command switches the synchronization status of the mirror data.

This command acquires the current right of hybrid disk resource.

This command is used to set whether mirror data is to be compressed.

This command switches the communication path (mirror disk connect) to be used.

### **Option**

#### **--active, -a**

Activates the hybrid disk resource on the local server.

If the status of hybrid disk resource is normal, mirroring is performed.

If the status of hybrid disk resource is not normal, mirroring will not be performed.

#### **-force (--active, -a)**

Forcibly activates a hybrid disk resource. This command can be run on a server where mirroring is stopped.

#### **-nomount**

It allows access to hybrid partition device without mounting the file system.

This option is used with the `--active` option.

This option has no meaning if none is specified for the file system.

#### **-ro**

Forcibly activates a mirror disk resource in ReadOnly mode.

This option is used with the `--active` `-force` options.

#### **--deactive, -d**

Deactivates the activated hybrid disk resource on the local server.

#### **--break, -b**

Disconnects the hybrid disk resources forcibly specified with *hybriddisk-alias* on the server where the command is run.

The status of the hybrid disk resource on the server where the command is run becomes an error.

The status of the hybrid disk resource on the server where the command is not run does not change.

When a mirror is recovered, disconnection is canceled.

Hybrid disk data is not synchronized even when any data is written to a hybrid disk.

Auto mirror recovery is not automatically started until reboot is performed or disconnection is canceled after completion of mirror recovery.

**--recovery, -r**

Performs either full mirror recovery or differential mirror recovery for the specified hybrid disk resource.

Whether to perform full or differential mirror recovery is determined automatically.

**--force, -f**

Forcefully performs mirror recovery for the specified hybrid disk resource.

If only *hybriddisk-alias* is specified, the status of the hybrid disk where the command is run becomes normal forcibly. Mirror resynchronization is not performed.

If *recovery-source-servername* and *hybriddisk-alias* are specified, full mirror recovery is performed using *recovery-source-servername* as source data. The status of the hybrid disk becomes normal when the full mirror recovery completes.

**-v**

Forcefully performs mirror recovery without an analysis of the file system.

**--cancel, -c**

Cancels mirror recovery.

If auto mirror recovery is set to ON and the hybrid disk monitor resource is operating, mirror recovery will be automatically restarted a short while after mirror recovery is canceled. In this case, first suspend the hybrid disk monitor resource with either Cluster WebUI or the *clpmonctrl* command and then cancel mirror recovery.

**--waitm, -w**

Waits for the completion of the mirror recovery of the specified disk resource.

**-timeout**

Specifies the timeout period of mirror recovery completion (second). This option can be omitted.

When this option is omitted, timeout is not executed and waits for the completion of mirror recovery.

**-rcancel**

Cancels mirror recovery when the timeout of waiting of mirror recovery completion occurred. This option can be set when *-timeout* option is set.

When this option is omitted, the mirror recovery continues even after the timeout occurrence.

**--getreq**

Displays the current maximum number of request queues.

**--setreq**

Configures the maximum number of request queues.

When the server shuts down, what you have configured here returns to the value set in the cluster configuration data. Use the Cluster WebUI if you want to modify the cluster configuration data. For details, see "[Cluster properties](#)" "[Mirror driver tab ~ For Replicator/Replicator DR ~](#)" in "[2. Parameter details](#)."

The command is only effective on the server that runs the command.

**--sync**

This option switches the operation to the mirror synchronization.

When the hybrid disk resource name is not specified, the operation is switched to synchronizing the mirror data to all hybrid resources.

**--nosync**

This option switched the operation to the one that does not synchronize the mirror data.

When the hybrid disk resource name is not specified, the operation is switched to not performing the synchronization of the mirror data to all hybrid resources.

However, the data updated to a disk during a mirror recovery is synchronized to a standby server.

If auto mirror recovery is set to ON and the mirror disk monitor resource is operating, automatic mirror recovery will operate.

Even after the completion of mirror recovery, the operation will still not synchronize. To cancel this, execute the command with the --sync option specified.

When the server is shut down, the state will return to the synchronization operation that is set in the cluster configuration information. To change the cluster configuration information, use the Cluster WebUI. For details, see "Mirror tab" in "Mirror disk resource tuning properties" in "[Details tab](#)" in "[Understanding Mirror disk resources](#)" in "[3. Group resource details](#)" in this guide.

**--setcur**

This option acquires the current right of hybrid disk resource specified by *hybriddisk-alias* on the server on which the command is executed.

**--compress, -p**

Temporarily switches on the compression mode of mirror transfer data.

If the synchronous mode of mirror data is "Synchronous", only the recovery transfer data is compressed.

If the synchronous mode of mirror data is "Asynchronous", both the asynchronous transfer data and the recovery transfer data are compressed

When the hybrid disk resource name is not specified, the operation is performed to all hybrid disk resources.

**--nocompress, -n**

Temporarily switches off the compression mode of mirror transfer data.

When the mirror disk resource name is not specified, the operation is performed to all hybrid disk resources.

**--mdcswitch, -s**

Switches the mirror connection to another mdc that has the specified priority.

If the priority is not specified, the mirror connection is switched to the mdc that has the next highest priority after the current mdc.

If the mirror connection is connected to the mdc that has the lowest priority, it is switched to the one that has the highest priority.

If the mirror connection has already been switched to the specified mdc, the command terminates normally without performing any processing.

If the specified mdc does not exist, an error occurs.

**--resize, -z**

Extends the size of the data partition of the hybrid disk resource.

The extension is available only when the status of the hybrid disk resource is normal.

**-force(--resize,-z)**

Use with the --resize option.

Forcibly executes the extension regardless of the state of the hybrid disk resource.

Using this option causes full copy to be executed at the next mirror recovery.

However, the extension with this option is not possible during mirror recovery.

**--updatekey**

Updates the encryption key without stopping the resource.

The execution of this option, after completing the update of the encryption key files for the current servers in both of the server groups, updates the key for the encryption.

At this time, mirroring in progress is suspended. As required, execute mirror recovery after the execution.

**Parameter**

**recovery-source-servername**

Specifies a server name of the copy source.

**hybriddisk-alias**

Specifies a hybrid disk resource name.

**request-count**

Specifies a maximum number of request queues. You can specify a number from 2048 through 65535.

**time**

Specifies the timeout period of mirror recovery completion (seconds).

**mdc-priority**

Specifies the priority of mdc.

This is not the priority number of mdc in whole cluster, but the priority number (1 or 2) of mdc used by the hybrid disk resource.

**partition-size**

Specifies the new size of data partition. For the unit, use the following symbol. If "500G" is specified, the size is extended to 500 gibibytes. If the symbol of the unit is not used, the amount is regarded as in byte.

- K (Kibi byte)
- M (Mibi byte)
- G (Gibi byte)

- T (Tebi byte)

#### Return Value

|             |                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Success                                                                                                                                                                                              |
| 255<br>(-1) | Failure                                                                                                                                                                                              |
| 254<br>(-2) | Target disk is not configuring mirror, or the mirror configuring failed on the process. (Only when --rwait option is specified, including the case when mirror recovery is interrupted by -rcancel.) |
| 253<br>(-3) | Timeout of mirror recovery of target disk occurs (Only when --rwait -timeout option is specified)                                                                                                    |

#### Remarks

*request-count*, which is displayed by specifying the --getreq option, is the same as "Max. Number of Request Queues" which is displayed by using the clpstat command.

```
# clpstat --cl --detail
```

This command returns control when the specified processing starts. Run the clphdstat command to check the processing status.

#### Notes

Run this command as the root user.

--active/--force (Forced mirror recovery) /--setcur can be executed on a server that has a current right or that can have a current right.

You can execute --recovery or --force (full mirror recovery with *recovery-source-servername* specified) in the following condition.

- The server of copy source has the current right or can have a current right.
- The server of copy target has the current right or can have a current right.  
(Mirror recovery cannot be performed on the server without current right in the cluster where hybrid disk resource is configured on the shared disk.)

--break/--cancel/--setreq/--sync/--nosync/--setreq can be executed on the server that has a current right.

For further information on the conditions for using this command to change the current server, see "[List of operations to switch a current server](#)".

When performing mirror recovery again after mirror recovery failed, specify the same server you used last time for mirror recovery as a copy source.

To resume the forced mirror recovery that was suspended by selecting **Cancel**, use this command for forced mirror recovery.

In a cluster with more than three nodes, if the server where the command is run is not included in a startup server of a group including hybrid disk resources, this command results in error. Do not run this command if the server is not included in a startup server of a group.

If, during mirror synchronization, mirror synchronization is interrupted with either the --break (-b) or --nosync option or if, during mirror recovery, mirror recovery is interrupted, the file system and application data may prove to be abnormal even if the mirror disk to be synchronized is made accessible by performing forced activation or forced mirror recovery. For details, see "Mirror data reference at the synchronization destination if mirror synchronization is interrupted" in "Notes and Restrictions" in the "Getting Started Guide".

#### Example of command execution

**Example 1:** When activating the hybrid disk resource hd1:

```
# clphdctrl --active hd1
<hd1@server1>: active successfully
```

**Example 2:** When deactivating the hybrid disk resource hd1:

```
# clphdctrl --deactive hd1
<hd1@server1>: deactive successfully
```

**Example 3:** When disconnecting the hybrid disk resource hd1:

```
# clphdctrl --break hd1
hd1: isolate successfully
```

**Example 4:** When the status of hybrid disks both servers is error, and you need to recover the operation that uses the resource hd1 (group name: failover1) as soon as possible:

```
# clphdctrl --force hd1
The data of mirror disk in local server maybe is not latest.
Do you still want to continue? (Y/N)
```

**Example 5:** When recovering mirroring of the hybrid disk resource hd1 :

```
# clphdctrl --recovery hd1
```

**Example 6:** When setting the maximum number of request queues to 2048:

```
# clphdctrl --setreq 2048
current I/O request count <2048>
```

**Example 7:** When configure the setting that does not perform the data synchronization to the hybrid disk resource hd1:

```
# clphdctrl --nosync hd1
```

## Error Messages

| Error: Mirror flag error. Use "clphdinit" to construct the mirror. The status of cluster partition of the hybrid disk resource is abnormal. When the server with the error has the latest data, backup the data, initialize the cluster partition, and replace the same disk by using the same disk. If the error persists, change the disk to new one. | The cluster partition of the hybrid disk resource has a problem. When the server with error has the latest data, back up the data, initialize the cluster partition according to Chapter 8 "Verifying Operation" in the Installation and Configuration Guide, and follow the same way as described in "How to replace a mirror disk with a new one" in Chapter 1, "The system maintenance information" in the maintenance guide, using the same disk. If this occurs again, replace the disk with a new disk. |
| Error: Both local and remote mirrors are active. Shut down the cluster and execute forced mirror recovery after rebooting the server.                                                                                                                                                                                                                   | Both systems are active. Shut down the cluster and perform forced mirror recovery after reactivating the server.                                                                                                                                                                                                                                                                                                                                                                                              |
| Error: Mirror Agent is not running. Check if the Mirror Agent is active.                                                                                                                                                                                                                                                                                | The Mirror Agent is not started up. Check to see if the Mirror Agent is running.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Error: System calls error. Failed to run the system command when active and/or inactive. Check if the search path is set to an environment variables.                                                                                                                                                                                                   | Running the system command when active/inactive has failed. Check to see if a search path is set as an environmental variable.                                                                                                                                                                                                                                                                                                                                                                                |
| Error: Failed to create a mount point. The disk space may not be sufficient.                                                                                                                                                                                                                                                                            | Creating a mount point has failed. Disk space may be insufficient. Check it.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: Timeout has occurred on active fsck. When it is not journaling file system, it may take time to run fsck if the size of data partition of hybrid disk is large. Set timeout of fsck longer.                                                                                                                                                      | fsck time-out has occurred. In case it is not the journaling file system, running fsck may take time when the data partition of the hybrid disk is large. Set the longer time for the fsck time-out using the Cluster WebUI.                                                                                                                                                                                                                                                                                  |
| Error: Timeout occurs at activation mount. Set mount timeout longer                                                                                                                                                                                                                                                                                     | Time-out has occurred at active mounting. Set the mounting time-out longer by using the Cluster WebUI.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Error: Timeout occurs at deactivation mount. Set unmount timeout longer.                                                                                                                                                                                                                                                                                | Time-out has occurred at inactive unmounting of the file system. Set the mount time-out period longer by using the Cluster WebUI.                                                                                                                                                                                                                                                                                                                                                                             |
| Error: fsck failed. Check if file system type of data partition does not match configuration file, fsck option is incorrect or partition is incorrect.                                                                                                                                                                                                  | Running fsck has failed. Check to see if the file system type of the data partition matches to the configuration file, fsck option is valid, and partition is not destroyed.                                                                                                                                                                                                                                                                                                                                  |
| Error: Failed to mount when active. The file system type of the data partition does not match the settings of the configuration file, or the partition may be corrupted.                                                                                                                                                                                | Mounting during activation has failed. Check to see if the file system type of the data partition matches to the configuration file, fsck option is valid, and the partition is not destroyed.                                                                                                                                                                                                                                                                                                                |
| Error: Failed to unmount when inactive. Check if the file system on the data partition is busy.                                                                                                                                                                                                                                                         | Unmount during deactivation has failed. Check to see if the file system on data partition is not busy.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Error: Hybrid disk resource is on process of activation. Execute after activation is completed.                                                                                                                                                                                                                                                         | The hybrid disk resource is in the process of activation. Try after activation is completed.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: Failed to perform forced mirror recovery or activate a single server. Check if any hardware error has occurred on the disk.                                                                                                                                                                                                                      | Performing forced recovery or activating a standalone server has failed. Check to see if any hardware error has occurred on the disk.                                                                                                                                                                                                                                                                                                                                                                         |

| Automatic mirror recovery is disabled. It is necessary to recover the mirror manually, in order to resume mirroring. | Succeeded in updating the encryption key. However, automatic mirror recovery is disabled and therefore resuming the mirroring requires manual mirror recovery. |

### List of operations to switch a current server

Current server is also switched when the following operations are performed with this command.

| Hybrid disk status |                           | Whether or not current server can be changed |                | Possible operation |                |
|--------------------|---------------------------|----------------------------------------------|----------------|--------------------|----------------|
| Server group 1     | Server group 2            | Server group 1                               | Server group 2 | Server group 1     | Server group 2 |
| normal/ inactive   | normal/ inactive          | Yes                                          | Yes            | 1                  | 1              |
| normal/ inactive   | error/ inactive           | Yes                                          | Yes            | 1                  | 1,3            |
| normal/ inactive   | error/ inactive           | No                                           | Yes            | -                  | 1,3            |
| error/ inactive    | error/ inactive           | Yes                                          | Yes            | 1,2,3              | 1,2,3          |
| error/ inactive    | error/ forcibly activated | Yes                                          | No             | 2,3                | -              |
| error/ inactive    | Unknown                   | Yes                                          | No             | 2,3                | -              |
| pending/ inactive  | pending/ inactive         | Yes                                          | Yes            | 1                  | 1              |
| pending/ inactive  | Unknown                   | Yes                                          | No             | 2                  | -              |

|   |                                                    |
|---|----------------------------------------------------|
| 1 | Recovering mirror (differential/entire data)       |
| 2 | Forcefully recovering mirror on one server         |
| 3 | Canceling access restriction (Forcible activation) |
| 4 | Disconnecting a mirror disk                        |

**Note:** See the online manual to perform the operations like those above on Cluster WebUI.

### 8.15.3 Initializing hybrid disks (clphdinit command)

the clphdinit command initializes a hybrid disk.

#### Command line

```
clphdinit {--create | -c} normal [hybriddisk-alias]
clphdinit {--create | -c} quick [hybriddisk-alias]
clphdinit {--create | -c} force [hybriddisk-alias]
```

---

**Important:** Generally you do not need to run this command when constructing or operating a cluster. You should exercise caution when you use this command because the partition used for the data will be initialized.

---

#### Description

This command initializes the cluster partition of a hybrid disk resource.

File systems are not created automatically to the data partition of the hybrid disk resource in this version. Create file systems in advance as necessary.

#### Option

**{--create, -c}** <mode>  
mode

##### **normal**

Initializes a cluster partition, if necessary.

The necessity is determined by the magic number set by EXPRESSCLUSTER on the cluster partition.

Generally, it is not necessary to run the command with this option.

##### **quick**

Initializes the cluster partition, if necessary.

Whether or not it is necessary to initialize the cluster partition is determined by the magic number set by EXPRESSCLUSTER on the cluster partition.

Generally, it is not necessary to run the command with this option.

##### **force Forcefully initializes the cluster partition.**

Forcefully initializes the cluster partition.

This option is used when using the disk that was once used as a hybrid disk of EXPRESSCLUSTER again.

#### Parameter

##### **hybriddisk-alias**

Specifies a hybrid disk resource name. If this parameter is not specified, the process is performed on all hybrid disk resources.

#### Return Value

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

## Notes

You should exercise caution when you run this command because the hybrid disk will be initialized.

When there are multiple servers in one server group, execute the command on one of the servers to initialize a cluster partition.

Run this command as the root user.

Do not run other commands, until this command is returned.

When running this command, make sure that the MirrorAgent is stopped in all servers in the cluster. To check the Hybrid Agent is stopped on all servers, run the following command:

```
# ps -e | grep clpmdagent
```

In a cluster with more than three nodes, if the server where the command is run is not included in a startup server of a group including hybrid disk resources, this command results in error. Do not run this command if the server is not included in a startup server of a group.

## Example of command execution

**Example 1:** When forcefully initializing the cluster partition because the disk to be used for the hybrid disk resource hdl was once used as a hybrid disk of EXPRESSCLUSTER:

```
# clphdinit --create force hdl
mirror info will be set as default
the main handle on initializing hybrid disk <hdl> success
initializing hybrid disk complete
```

## Error Messages

See 8.14.5. "*Perform the processing after restoring from a disk image (clprestore.sh command)*".

## 8.16 Outputting messages (clplogcmd command)

the clplogcmd command registers the specified message with syslog and alert, reports the message by mail, or sends it as an SNMP trap.

### Command line

```
clplogcmd -m message [--syslog] [--alert] [--mail] [--trap] [-i eventID] [-l level]
```

---

**Note:** Generally, it is not necessary to run this command for constructing or operating the cluster. You need to write the command in the exec resource script.

---

### Description

Write this command in the exec resource script and output messages you want to send to the destination.

### Options

**-m** *message*

Specifies a message. This option cannot be omitted. The maximum size of message is 511 bytes. (When syslog is specified as an output destination, the maximum size is 485 bytes.) The message exceeding the maximum size will not be shown.

You may use alphabets, numbers, and symbols. See below<sup>7</sup> for notes on them.

**--syslog**

**--alert**

**--mail**

**--trap**

Specify the output destination from syslog, alert, mail, and trap. (Multiple destinations can be specified.)

This parameter can be omitted. The syslog and alert will be the output destinations when the parameter is omitted.

For more information on output destinations, see "Directory structure of EXPRESSCLUSTER" in "The system maintenance information" in the "Maintenance Guide".

**-i** *eventID*

Specify event ID. The maximum value of event ID is 10000.

This parameter can be omitted. The default value 1 is set when the parameter is omitted.

**-l** *level*

Select a level of alert output from ERR, WARN, or INFO. The icon on the alert logs of the Cluster WebUI is determined according to the level you select here.

---

#### <sup>7</sup> Notes on using symbols in the message:

The symbols below must be enclosed in double quotes (" "):

# & ' ( ) ~ | ; : \* < > , .

(For example, if you specify "#" in the message, # is produced.)

The symbols below must have a backslash \ in the beginning:

\ ! " & ' ( ) ~ | ; : \* < > , .

(For example, if you specify \ in the message, \ is produced.)

The symbol that must be enclosed in double quotes (" ") and have a backslash \ in the beginning:

(For example, if you specify "\" in the message, ` will be produced.)

- When there is a space in the **message**, it must be placed in enclosed in double quotes (" ").
- The symbol % cannot be used in the **message**.

This parameter can be omitted. The default value INFO is set when the parameter is omitted. For more information, see the online manual.

#### Return Value

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

#### Notes

Run this command as the root user.

When mail is specified as the output destination, you need to make the settings to send mails by using the mail command.

#### Example of command execution

**Example 1:** When specifying only message (output destinations are syslog and alert):

When the following is written in the exec resource script, the **message** is produced in syslog and alert.

```
clplogcmd -m test1.
```

The following log is the log output in syslog:

```
Sep 1 14:00:00 server1 expresscls: <type: logcmd><event: 1> test1
```

**Example 2:** When specifying message, output destination, event ID, and level (output destination is mail):

When the following is written in the exec resource script, the message is sent to the mail address set in the **Cluster Properties**. For more information on the mail address settings, see "[Alert Service tab](#)" in "[Cluster properties](#)" in "[2. Parameter details](#)" in this guide.

```
clplogcmd -m test2 --mail -i 100 -l ERR
```

The following information is sent to the mail destination:

```
Message:test2
Type: logcmd
ID: 100
Host: server1
Date: 2004/09/01 14:00:00
```

**Example 3:** When specifying a message, output destination, event ID, and level (output destination is trap):

When the following is written in the exec resource script, the message is set to the SNMP trap destination set in **Cluster Properties** of the Cluster WebUI. For more information on the SNMP trap destination settings, see "[Alert Service tab](#)" in "[Cluster properties](#)" in "[2. Parameter details](#)" in this guide.

```
clplogcmd -m test3 --trap -i 200 -l ERR
```

The following information is sent to the SNMP trap destination:

```
Trap OID: clusterEventError
Attached data 1: clusterEventMessage = test3
Attached data 2: clusterEventID = 200
Attached data 3: clusterEventDateTime = 2011/08/01 09:00:00
Attached data 4: clusterEventServerName = server1
Attached data 5: clusterEventModuleName = logcmd
```

## 8.17 Controlling monitor resources (clpmonctrl command)

the clpmonctrl command controls the monitor resources.

### Command line

```
clpmonctrl -s [-h <hostname>] [-m resource_name] [-w wait_time]
clpmonctrl -r [-h <hostname>] [-m resource_name] [-w wait_time]
clpmonctrl -c [-m resource_name]
clpmonctrl -v [-m resource_name]
clpmonctrl -e [-h <hostname>] -m resource_name
clpmonctrl -n [-h <hostname>] [-m resource_name]
```

---

### Note:

The -c and -v options must be run on all servers that control monitoring because the command controls the monitor resources on a single server.

It is recommended to use the Cluster WebUI if you suspend or resume monitor resources on all the servers in a cluster.

---

### Description

This command suspends and/or resumes the monitor resources, displays and/or resets the times counter of the recovery action, and enable and/or disable Dummy Failure.

### Option

- |                         |                                                                                                                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-s</b>               | Suspends monitoring                                                                                                                                                                                                          |
| <b>-r</b>               | Resumes monitoring                                                                                                                                                                                                           |
| <b>-c</b>               | Resets the times counter of the recovery action.                                                                                                                                                                             |
| <b>-v</b>               | Displays the times counter of the recovery action.                                                                                                                                                                           |
| <b>-e</b>               | Enables the Dummy Failure. Be sure to specify a monitor resource name with the -m option.                                                                                                                                    |
| <b>-n</b>               | Disables the Dummy Failure. When a monitor resource name is specified with the -m option, the function is disabled only for the resource. When the -m option is omitted, the function is disabled for all monitor resources. |
| <b>-m</b> resource_name | Specifies a monitor resource to be controlled.<br>This option can be omitted. All monitor resources are controlled when the option is omitted.                                                                               |
| <b>-w</b> wait_time     | Waits for control monitoring on a monitor resource basis (in seconds).                                                                                                                                                       |

This option can be omitted. The default value 5 is set when the option is omitted.

**-h**

Makes a processing request to the server specified in hostname. Makes a processing request to the server on which this command runs (local server) if the -h option is omitted. The -c and -v options cannot specify the server.

**Return Value**

|     |                                           |
|-----|-------------------------------------------|
| 0   | Normal termination                        |
| 1   | Privilege for execution is invalid        |
| 2   | The option is invalid                     |
| 3   | Initialization error                      |
| 4   | The cluster configuration data is invalid |
| 5   | Monitor resource is not registered.       |
| 6   | The specified monitor resource is invalid |
| 10  | The cluster is not activated              |
| 11  | The cluster daemon is suspended           |
| 12  | Waiting for cluster synchronization       |
| 90  | Monitoring control wait time-out          |
| 128 | Duplicated activation                     |
| 200 | Server connection error                   |
| 201 | Invalid status                            |
| 202 | Invalid server name                       |
| 255 | Other internal error                      |

**Example of command execution**

**Example 1:** When suspending all monitor resources:

```
# clpmonctrl -s  
Command succeeded.
```

**Example 2:** When resuming all monitor resources:

```
# clpmonctrl -r  
Command succeeded.
```

**Remarks**

If you suspend a monitor resource that is already suspended or resume that is already resumed, this command terminates with error, without changing the status of the monitor resource.

**Notes**

Run this command as the root user.

Check the status of monitor resource by using the status display clpstat command or Cluster WebUI.

Before you run this command, use the clpstat command or Cluster WebUI to verify that the status of monitor resources is in either "Online" or "Suspend."

If the recovery action for the monitor resource is set as follows, "Final Action Count", which displayed by the -v option, means the number of times "Execute Script before Final Action" is executed.

- Execute Script before Final Action: Enable
- final action: No Operation

**Error Messages**

## 8.18 Controlling group resources (clprsc command)

the clprsc command controls group resources

**Command line**

```
clprsc -s resource_name [-h hostname] [-f] [--apito timeout]
clprsc -t resource_name [-h hostname] [-f] [--apito timeout]
clprsc -n resource_name
clprsc -v resource_name
```

**Description**

This command starts and stops group resources.

**Option**

- s**  
Starts group resources.
- t**  
Stops group resources.
- h**  
Requests processing to the server specified by the hostname.  
When this option is skipped, request for processing is made to the following servers.
  - When the group is offline, the command execution server (local server).
  - When the group is online, the server where group is activated.
- f**  
When the group resource is online, all group resources that the specified group resource depends starts up.  
When the group resource is offline, all group resources that the specified group resource depends stop.
- n**  
Displays the name of the server on which the group resource has been started.
- apito timeout**  
Specify the interval (internal communication timeout) to wait for the group resource start or stop in seconds. A value from 1 to 9999 can be specified.  
  
If the --apito option is not specified, waiting for the group resource start or stop is performed according to the value set to the internal communication timeout of the cluster properties.
- v**  
Displays the failover counter of the group resource.

**Return Value**

|              |         |
|--------------|---------|
| 0            | success |
| Other than 0 | failure |

**Example**

Group resource configuration

```
# clpstat

<Abbreviation>
```

**Notes**

Run this command as a user with root privileges.

Check the status of the group resources by the status display or the Cluster WebUI.

When there is an active group resource in the group, the group resources that are offline cannot be started on another server.

**Error Messages**

| Message                                                                                              | Causes/Solution                                                                                                   |

| Message                                                                                                                                  | Causes/Solution                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal communication timeout has occurred in the cluster server. If it occurs frequently, set the longer timeout.                      | Timeout has occurred in internal communication in the EXPRESSCLUSTER.<br>Set the internal communication timeout longer if this error occurs frequently.                                            |
| The group resource is busy. Try again later.                                                                                             | Because the group resource is in the process of starting or stopping, wait for a while and try again.                                                                                              |
| An error occurred on group resource. Check the status of group resource.                                                                 | Check the group resource status by using the Cluster WebUI or the clpstat command.                                                                                                                 |
| Could not start the group resource. Try it again after the other server is started, or after the Wait Synchronization time is timed out. | Wait until the other server starts or the wait time times out, and then start the group resources.                                                                                                 |
| No operable group resource exists in the server.                                                                                         | Check there is a processable group resource on the specified server.                                                                                                                               |
| The group resource has already been started on the local server.                                                                         | Check the group resource status by using the Cluster WebUI or clpstat command.                                                                                                                     |
| The group resource has already been started on the other server.                                                                         | Check the group resource status by using the Cluster WebUI or clpstat command.<br>Stop the group to start the group resources on the local server.                                                 |
| The group resource has already been stopped.                                                                                             | Check the group resource status by using the Cluster WebUI or clpstat command.                                                                                                                     |
| Failed to start group resource. Check the status of group resource.                                                                      | Check the group resource status by using the Cluster WebUI or clpstat command.                                                                                                                     |
| Failed to stop resource. Check the status of group resource.                                                                             | Check the group resource status by using the Cluster WebUI or clpstat command.                                                                                                                     |
| Depended resource is not offline. Check the status of resource.                                                                          | Because the status of the depended group resource is not offline, the group resource cannot be stopped. Stop the depended group resource or specify the -f option.                                 |
| Depending resource is not online. Check the status of resource.                                                                          | Because the status of the depended group is not online, the group resource cannot be started. Start the depended group resource or specify the -f option.                                          |
| Invalid group resource name. Specify a valid group resource name in the cluster.                                                         | The group resource is not registered.                                                                                                                                                              |
| Server is not in a condition to start resource or any critical monitor error is detected.                                                | Check the group resource status by using the Cluster WebUI or clpstat command.<br>An error is detected in a critical monitor on the server on which an attempt to start a group resource was made. |
| Internal error. Check if memory or OS resources are sufficient.                                                                          | Memory or OS resources may be insufficient. Check them.                                                                                                                                            |

## 8.19 Controlling reboot count (clpregctrl command)

the clpregctrl command controls reboot count limitation.

### Command line

```
clpregctrl --get
clpregctrl -g
clpregctrl --clear -t type -r registry
clpregctrl -c -t type -r registry
```

---

**Note:** This command must be run on all servers that control the reboot count limitation because the command controls the reboot count limitation on a single server.

---

### Description

This command displays and/or initializes reboot count on a single server.

### Option

**-g, --get**  
Displays reboot count information.

**-c, --clear**  
Initializes reboot count.

**-t type**  
Specifies the type to initialize the reboot count. The type that can be specified is *rc* or *rm*.

**-r registry**  
Specifies the registry name. The registry name that can be specified is *haltcount*.

### Return Value

|          |                                                |
|----------|------------------------------------------------|
| 0        | Normal termination                             |
| 1        | Privilege for execution is invalid             |
| 2        | Duplicated activation                          |
| 3        | Option is invalid                              |
| 4        | The cluster configuration data is invalid      |
| 10 to 17 | Internal error                                 |
| 20 to 22 | Obtaining reboot count information has failed. |
| 90       | Allocating memory has failed.                  |
| 91       | Changing the work directory as failed.         |

### Example of command execution

Display of reboot count information

```
# clpregctrl -g
```

```
*****
-----
type      : rc
registry  : haltcount
```

(continues on next page)

(continued from previous page)

```

comment      : halt count
kind         : int
value        : 0
default      : 0

-----

type         : rm
registry     : haltcount
comment      : halt count
kind         : int
value        : 3
default      : 0

*****
Command succeeded. (code:0)

```

The reboot count is initialized in the following examples.

Run this command on server2 when you want to control the reboot count of server2.

**Example1:** When initializing the count of reboots caused by group resource error:

```

# clpregctrl -c -t rc -r haltcount
Command succeeded. (code:0)
#

```

**Example2:** When initializing the count of reboots caused by monitor resource error:

```

# clpregctrl -c -t rm -r haltcount
Command succeeded. (code:0)
#

```

#### Remarks

For information on the reboot count limit, see "*Attributes common to group resources*" "*Reboot count limit*" in "*3. Group resource details*" in this guide.

#### Notes

Run this command as the root user.

#### Error Messages

| Message                                                                                                     | Causes/Solution                                                                                 |

| Internal error. Check if memory or OS resources are sufficient.                                             | Check to see if the memory or OS resource is sufficient.                                        |

## 8.20 Turning off warning light (clplamp command)

The clplamp command turns the warning light off.

### Command line

`clplamp -h hostname`

### Description

Turns the warning light of the specified server off.

If the reproduction of audio file is set, audio file reproduction is stopped.

### Option

`-h hostname`

Specify a server whose warning light you want to turn off.

### Return Value

|              |                      |
|--------------|----------------------|
| 0            | Normal termination   |
| Other than 0 | Abnormal termination |

### Example

**Example 1: When turning off the warning light and audio alert for server1**

```
# clplamp -h server1
```

Command succeeded

### Notes

This command should be performed by the user with root privilege.

## 8.21 Controlling CPU frequency (clpcpufreq command)

The clpcpufreq command controls CPU frequency.

### Command line:

```
clpcpufreq --high [-h hostname]  
clpcpufreq --low [-h hostname]  
clpcpufreq -i [-h hostname]  
clpcpufreq -s [-h hostname]
```

### Description

This command enables/disables power-saving mode by CPU frequency control.

### Option

**--high**  
Sets CPU frequency to highest.

**--low**  
Sets CPU frequency to lowest.

**-i**  
Switch to automatic control by cluster.

**-s**  
Displays the current CPU frequency level.

- high: Frequency is highest
- low: Frequency is lowered and it is in power-saving mode

**-h *hostname***  
Requests the server specified in *hostname* for processing.  
If this is omitted, it requests the local server for processing.

### Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

### Example

```
# clpcpufreq -s  
performance  
Command succeeded.  
  
# clpcpufreq --high  
Command succeeded.  
  
# clpcpufreq --low -h server1  
Command succeeded.  
  
# clpcpufreq -i  
Command succeeded
```

### Remark

If the driver for CPU frequency control is not loaded, an error occurs.

If the Use CPU Frequency Control checkbox is not selected in the power saving settings in cluster properties, this command results in error.

**Notes**

This command must be executed by a user with the root privilege.

When you use CPU frequency control, it is required that frequency is changeable in the BIOS settings, and that the CPU supports frequency control by Windows OS power management function.

**Error Messages**

## 8.22 Controlling chassis identify lamp (clpledctrl command)

The clpledctrl command controls the chassis identify function.

### Command line

```
clpledctrl -d [-h hostname] [-a] [-w timeout]  
clpledctrl -i [-h hostname] [-a] [-w timeout]
```

### Description

This command disables/enables chassis identify function.

### Option

- d**  
Disables the chassis identify function.
- i**  
Enables the chassis identify function.
- h *hostname***  
Specifies the name of the server which enables/disables the chassis identify function. Specify -a to omit this.
- a**  
All servers in the cluster are the targets.  
The -a option can be omitted. If so, specify hostname.
- w *timeout***  
Specifies the timeout value of the command by the second.  
If the -w option is not specified, it waits for 30 seconds.

### Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

### Notes

This command must be executed by a user with the root privilege.

Execute this command in the server operating normally in the same cluster as the one which the target server belongs to.

If you disable the chassis identify function by this command, it is canceled when the cluster is restarted or when the target server recovers the normal status.

### Examples

**Example 1: When disabling (i.e. turn off the lamp which is turned on) the chassis identify function in server1 (specify the command timeout as 60 seconds)**

```
# clpledctrl -d server1 -w 60
```

**Example 2: When disabling chassis identify in all servers in the cluster**

```
# clpledctrl -d -a
```

**Example 3: When enabling the chassis identify function in server1 where the function was disabled**

```
# clpledctrl -i server1
```

The result of command execution is displayed as follows:

Detail of the processing Server name: Result (Cause if failed)

**Error messages**

## 8.23 Processing inter-cluster linkage (clptrnreq command)

The clptrnreq command requests a server to execute a process.

### Command line

```
clptrnreq -t request_code -h IP [-r resource_name] [-s script_file] [-w timeout]
```

### Description

The command issues the request to execute specified process to the server in another cluster.

### Option

**-t** *request\_code*

Specifies the request code of the process to be executed.

The following request codes can be specified:

GRP\_FAILOVER Group failover  
EXEC\_SCRIPT Execute script

**-h** IP

Specifies the server to issue the request to execute the process with IP address. You can specify more than one server by separating by commas.

When you specify group failover for request code, specify the IP addresses of all the servers in the cluster.

**-r** *resource\_name*

Specifies the resource name which belongs to the target group for the request for process when GRP\_FAILOVER is specified for request code.

If GRP\_FAILOVER is specified, -r cannot be omitted.

**-s** *script\_file*

Specifies the file name of the script to be executed (e.g. batch file or executable file) when EXEC\_SCRIPT is specified for request code.

The script needs to be created in the work\trnreq folder in the folder where EXPRESSCLUSTER is installed in each server specified with -h.de.

If EXEC\_SCRIPT is specified, -s cannot be omitted.

**-w** *timeout*

Specifies the timeout value of the command by the second.

If the -w option is not specified, the command waits 30 seconds.

### Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

### Notes

This command must be executed by a user with the root privilege.

### Examples

**Example 1:** When performing a failover on the group having the exec1 resource of another cluster

```
# clptrnreq -t GRP_FAILOVER -h 10.0.0.1,10.0.0.2 -r exec1
Command succeeded.
```

**Example 2: When executing the script1.bat script by the server with IP address 10.0.0.1**

```
# clptrnreq -t EXEC_SCRIPT -h 10.0.0.1 -s script1.bat
Command Succeeded.
```

**Error messages**

| Message                                                                                  | Cause/solution                                                                                                                                             |

## 8.24 Requesting processing to cluster servers (clprexec command)

This command requests a server to execute a process.

### Command line

```
clprexec --failover ( [group_name] | [-r resource_name] ) -h IP [-w timeout] [-p port_number] [-o logfile_path]
clprexec --script script_file -h IP [-p port_number] [-w timeout] [-o logfile_path]
clprexec --notice ( [mrw_name] | [-k category[keyword]] ) -h IP [-p port_number] [-w timeout] [-o logfile_path]
clprexec --clear ( [mrw_name] | [-k category[keyword]] ) -h IP [-p port_number] [-w timeout] [-o logfile_path]
```

### Description

This command is an expansion of the existing clptnreq command and has additional functions such as issuing a processing request (error message) from the external monitor to the EXPRESSCLUSTER server.

### Option

#### --failover

Requests group failover. Specify a group name for *group\_name*.

When not specifying the group name, specify the name of a resource that belongs to the group by using the -r option.

#### --script script\_name

Requests script execution.

For *script\_name*, specify the file name of the script to execute (such as a shell script or executable file).

The script must be created in the work/rexec directory, which is in the directory where EXPRESSCLUSTER is installed, on each server specified using -h.

#### --notice

Sends an error message to the EXPRESSCLUSTER server.

Specify a message receive monitor resource name for *mrw\_name*.

When not specifying the monitor resource name, specify the category and keyword of the message receive monitor resource by using the -k option.

#### --clear

Requests changing the status of the message receive monitor resource from "Abnormal" to "Normal."

Specify a message receive monitor resource name for *mrw\_name*.

When not specifying the monitor resource name, specify the category and keyword of the message receive monitor resource by using the -k option.

#### -h IP Address

Specify the IP addresses of EXPRESSCLUSTER servers that receive the processing request.

Up to 32 IP addresses can be specified by separating them with commas.

\* If this option is omitted, the processing request is issued to the local server.

#### -r resource\_name

Specify the name of a resource that belongs to the target group for the processing request when the --failover option is specified.

**-k** *category*[.*keyword*]

For *category*, specify the category specified for the message receive monitor when the --notice or --clear option is specified.

To specify the keyword of the message receive monitor resource, specify them by separating them with dot after *category*.

**-p** *port\_number*

Specify the port number.

For *port\_number*, specify the data transfer port number specified for the server that receives the processing request.

The default value, 29002, is used if this option is omitted.

**-o** *logfile\_path*

For *logfile\_path*, specify the file path along which the detailed log of this command is output.

The file contains the log of one command execution.

\* If this option is not specified on a server where EXPRESSCLUSTER is not installed, the log is always output to the standard output.

**-w** *timeout*

Specify the command timeout time. The default, 180 seconds, is used if this option is not specified.

A value from 5 to MAXINT can be specified.

## Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

## Notes

When issuing error messages by using the clprexec command, the message receive monitor resources for which an action to take in EXPRESSCLUSTER server when an error occurs is specified must be registered and started.

The server that has the IP address specified for the -h option must satisfy the following conditions:

- EXPRESSCLUSTER X3.0 or later must be installed.
- EXPRESSCLUSTER must be running.  
(When an option other than --script is used)
- mrw must be set up and running.  
(When the --notice or --clear option is used)

When using the **Controlling connection by using client IP address function**, add the IP address of the device in which the clprexec command is executed to the IP Addresses of the Accessible Clients list.

For details of the Controlling connection by using client IP address function, see "[WebManager tab](#)" in "[Cluster properties](#)" in "[2. Parameter details](#)" in this guide.

## Examples

**Example 1:** This example shows how to issue a request to fail over the group failover1 to EXPRESSCLUSTER server 1 (10.0.0.1):

```
# clprexec --failover failover1 -h 10.0.0.1 -p 29002
```

**Example 2:** This example shows how to issue a request to fail over the group to which the group resource (exec1) belongs to EXPRESSCLUSTER server 1 (10.0.0.1):

```
# clprexec --failover -r exec1 -h 10.0.0.1
```

**Example 3:** This example shows how to issue a request to execute the script (script1.sh) on EXPRESSCLUSTER server 1 (10.0.0.1):

```
# clprexec --script script1.sh -h 10.0.0.1
```

**Example 4:** This example shows how to issue an error message to EXPRESSCLUSTER server 1 (10.0.0.1):

```
*mrw1 set, category: earthquake, keyword: scale3
```

- This example shows how to specify a message receive monitor resource name:

```
# clprexec --notice mrw1 -h 10.0.0.1 -w 30 -p /tmp/clprexec/ ↵  
↳lprexec.log
```

- This example shows how to specify the category and keyword specified for the message receive monitor resource:

```
# clprexec --notice -k earthquake.scale3 -h 10.0.0.1 -w 30 -p /tmp/ ↵  
↳clprexec/clprexec.log
```

**Example 5:** This example shows how to issue a request to change the monitor status of mrw1 to EXPRESSCLUSTER server 1 (10.0.0.1):

```
*mrw1 set, category: earthquake, keyword: scale3
```

- This example shows how to specify a message receive monitor resource name:

```
# clprexec --clear mrw1 -h 10.0.0.1
```

- This example shows how to specify the category and keyword specified for the message receive monitor resource:

```
# clprexec --clear -k earthquake.scale3 -h 10.0.0.1
```

## 8.25 Changing BMC information (clpbmccnf command)

The clpbmccnf command changes the information on BMC user name and password.

### Command line

```
clpbmccnf [-u username] [-p password]
```

### Description

This command changes the user name/password for the LAN access of the baseboard management controller (BMC) which EXPRESSCLUSTER uses for chassis identify or forced stop.

### Option

**-u** *username*

Specifies the user name for BMC LAN access used by EXPRESSCLUSTER. A user name with root privilege needs to be specified.

The -u option can be omitted. Upon omission, when the -p option is specified, the value currently set for user name is used. If there is no option specified, it is configured interactively.

**-p** *password*

Specifies the password for BMC LAN access used by EXPRESSCLUSTER. The -p option can be omitted.

Upon omission, when the -u option is specified, the value currently set for password is used. If there is no option specified, it is configured interactively.

### Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

### Notes

This command must be executed by a user with root privilege.

Execute this command when the cluster is in normal status.

BMC information update by this command is enabled when the cluster is started/resumed next time.

This command does not change the BMC settings. Use a tool attached with the server or other tools in conformity with IPMI standard to check or change the BMC account settings.

### Examples

When you changed the IPMI account password of the BMC in server1 to mypassword, execute the following on server1:

```
# clpbmccnf -p mypassword
```

Alternatively, enter the data interactively as follows:

```
# clpbmccnf
```

```
New user name: <- If there is no change, press Return to skip
```

```
New password: *****
```

```
Retype new password: *****
```

```
Cluster configuration updated successfully.
```

### Error messages

## 8.26 Controlling cluster activation synchronization wait processing (clpbwctrl command)

The clpbwctrl command controls the cluster activation synchronization wait processing.

### Command line

```
clpbwctrl -c
clpbwctrl --np [on|off]
clpbwctrl -h
```

---

**Note:** The command with the --np option must be executed on all the servers that control the processing because the command controls the processing on a single server.

---

### Description

This command skips the cluster activation synchronization wait time that occurs if the server is started when the cluster services for all the servers in the cluster are stopped.

Specifies whether to execute the NP resolution process when the cluster is started on a single server.

### Option

**-c, --cancel**

Cancels the cluster activation synchronization wait processing.

**--np** [on|off]

Specifies whether to execute the NP resolution process when the cluster is started. When "on" is specified, the NP resolution process is executed. When "off" is specified, it is not executed.

[on|off] is optional. When omitted, the current setting is displayed.

**-h, --help**

Displays the usage.

### Return Value

|              |                              |
|--------------|------------------------------|
| 0            | Completed successfully.      |
| Other than 0 | Terminated due to a failure. |

### Notes

This command must be executed by a user with root privileges.

### Examples

This example shows how to cancel the cluster activation synchronization wait processing:

```
# clpbwctrl -c
Command succeeded.
```

The NP resolution process is not performed at the cluster startup:

```
# clpbwctrl --np off
Command succeeded.
```

```
# clpbwctrl --np
```

Resolve network partition on startup : off

## 8.27 Estimating the amount of resource usage (clpprer command)

Estimates the future value from the transition of the resource use amount data listed in the input file, and then outputs the estimate data to a file. Also, the result of threshold judgment on the estimate data can be confirmed.

### Command line

```
clpprer -i inputfile -o outputfile [-p number] [-t number [-l]]
```

### Description

Estimates the future value from the tendency of the given resource use amount data.

### Option

- i** *inputfile*  
Specifies the resource data for which a future value is to be obtained.
- o** *outputfile*  
Specifies the name of the file to which the estimate result is output.
- p** *number*  
Specifies the number of estimate data items.  
If omitted, 30 items of estimate data are obtained.
- t** *number*  
Specifies the threshold to be compared with the estimate data.
- l**  
Valid only when the threshold is set with the -t option. Judges the status to be an error when the data value is less than the threshold.

### Return Value

|   |                                                                                                                                                                                                                      |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Normal end without threshold judgment                                                                                                                                                                                |
| 1 | Error occurrence                                                                                                                                                                                                     |
| 2 | As a result of threshold judgment, the input data is determined to have exceeded the threshold.                                                                                                                      |
| 3 | As a result of threshold judgment, the estimate data is determined to have exceeded the threshold.                                                                                                                   |
| 4 | As a result of threshold judgment, the data is determined to have not exceeded the threshold.                                                                                                                        |
| 5 | If the number of data items to be analyzed is less than the recommended number of data items to be analyzed (120), the input data is determined to have exceeded the threshold as a result of threshold judgment.    |
| 6 | If the number of data items to be analyzed is less than the recommended number of data items to be analyzed (120), the estimate data is determined to have exceeded the threshold as a result of threshold judgment. |
| 7 | If the number of data items to be analyzed is less than the recommended number of data items to be analyzed (120), the data is determined to have not exceeded the threshold as a result of threshold judgment.      |

### Notes

This command can be used only when the license for the system monitor resource (System Resource Agent) is registered. (If the license is registered, you do not have to set up the system monitor resource when configuring a cluster.)

The maximum number of input data items of the resource data file specified with the -i option is 500. A certain number of input data items are required to estimate the amount of resource usage. However, if the number of input data items is large, it takes a considerable amount of time to perform the analysis. So, it is recommended

that the number of input data items be restricted to about 120. Moreover, the maximum number of output data items that can be specified in option -p is 500.

If the time data for the input file is not arranged in ascending order, the estimate will not be appropriate. In the input file, therefore, set the time data arranged in ascending order.

### Input file

The input file format is explained below. Prepare an input file which contains the resource usage data for which to obtain an estimate, in the following format.

The input file format is CSV. One piece of data is coded in the form of *date and time, numeric value*.

Moreover, the data and time format is *YYYY/MM/DD hh:mm:ss*.

File example

```
2012/06/14 10:00:00,10.0  
2012/06/14 10:01:00,10.5  
2012/06/14 10:02:00,11.0
```

### Examples

The estimation of the future value is explained using a simple example.

#### When an error is detected in the input data:

If the latest value of the input data exceeds the threshold, an error is assumed and a return value of 2 is returned.

If the number of input data items is less than the recommended value (=120), a return value of 5 is returned.

Fig. 8.7: Error detection in the input data

#### When an error is detected in the estimate data:

If the estimate data exceeds the threshold, an error is assumed and a return value of 3 is returned. If the number of input data items is less than the recommended value (=120), a return value of 6 is returned.

Fig. 8.8: Error detection in the estimate data

**When no threshold error is detected:**

If neither the input data nor the estimate data exceeds the threshold, a return value of 4 is returned. If the number of input data items is less than the recommended value (=120), a return value of 7 is returned.

Fig. 8.9: When no threshold error is detected

**When the -l option is used:**

If the -l option is used, an error is assumed when the data is less than the threshold.

Fig. 8.10: Use of the -l option

**Examples**

Prepare a file which contains data in the specified format, and then execute the clpprer command. The estimate result can be confirmed as the output file.

Input file: test.csv

```
2012/06/14 10:00:00,10.0
2012/06/14 10:01:00,10.5
2012/06/14 10:02:00,11.0
```

# clpprer -i test.csv -o result.csv

Output result: result.csv

```
2012/06/14 10:03:00,11.5
2012/06/14 10:04:00,12.0
2012/06/14 10:05:00,12.5
2012/06/14 10:06:00,13.0
2012/06/14 10:07:00,13.5
:
```

Also, by specifying a threshold as an option, you can confirm the threshold judgment result for the estimate at the command prompt.

# clpprer -i test.csv -o result.csv -t 12.5

Execution result

Detect over threshold. datetime = 2012/06/14 10:06:00, data = 13.00, threshold = 12.5

## 8.28 Checking the process health (clphealthchk command)

Checks the process health.

### Command line

```
clphealthchk [ -t pm | -t rc | -t rm | -t nm | -h ]
```

---

**Note:** This command must be run on the server whose process health is to be checked because this command checks the process health of a single server.

---

### Description

This command checks the process health of a single server.

### Option

#### None

Checks the health of all of pm, rc, rm, and nm.

**-t** <process>  
process

**pm** Checks the health of pm.

**rc** Checks the health of rc.

**rm** Checks the health of rm.

**nm** Checks the health of nm.

#### -h

Displays the usage.

### Return Value

|     |                                                                                                                                                                                                                     |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Normal termination                                                                                                                                                                                                  |
| 1   | Privilege for execution is invalid                                                                                                                                                                                  |
| 2   | Duplicated activation                                                                                                                                                                                               |
| 3   | Initialization error                                                                                                                                                                                                |
| 4   | The option is invalid                                                                                                                                                                                               |
| 10  | The process stall monitoring function has not been enabled.                                                                                                                                                         |
| 11  | The cluster is not activated (waiting for the cluster to start or the cluster has been stopped.)                                                                                                                    |
| 12  | The cluster daemon is suspended                                                                                                                                                                                     |
| 100 | There is a process whose health information has not been updated within a certain period.<br>If the -t option is specified, the health information of the specified process is not updated within a certain period. |
| 255 | Other internal error                                                                                                                                                                                                |

### Examples

**Example 1:** When the processes are healthy

```
# clphealthchk
pm OK
rc NG
rm OK
nm OK
```

**Example 2:** When clprc is stalled

```
# clphealthchk
pm OK
rc NG
rm OK
nm OK

# clphealthchk -t rc
rc NG
```

**Example 3:** When the cluster has been stopped

```
# clphealthchk
The cluster has been stopped
```

**Remarks**

If the cluster has been stopped or suspended, the process is also stopped.

**Notes**

Run this command as the root user.

**Error Messages**

## 8.29 Controlling the rest point of DB2 (clpdb2still command)

Controls the rest point of DB2.

### Command line

```
clpdb2still -d databasename -u username -s  
clpdb2still -d databasename -u username -r
```

### Description

Controls the securing/release of the rest point of DB2.

### Option

**-d** *databasename*  
Specifies the name of the target database for the rest point control.

**-u** *username*  
Specifies the name of a user who executes the rest point control.

**-s**  
Secures the rest point.

**-r**  
Releases the rest point.

### Return Value

|   |                                   |
|---|-----------------------------------|
| 0 | Normal completion                 |
| 2 | Invalid command option            |
| 5 | Failed to secure the rest point.  |
| 6 | Failed to release the rest point. |

### Examples

```
# clpdb2still -d sample -u db2inst1 -s
```

Database Connection Information

Database server = DB2/LINUX8664 11.1.0

SQL authorization ID = DB2INST1

Local database alias = SAMPLE

DB20000I The SET WRITE command completed successfully.

DB20000I The SQL command completed successfully.

DB20000I The SQL DISCONNECT command completed successfully.

```
# clpdb2still -d sample -u db2inst1 -r
```

Database Connection Information

Database server = DB2/LINUX8664 11.1.0

SQL authorization ID = DB2INST1

Local database alias = SAMPLE

DB20000I The SET WRITE command completed successfully.

```
DB20000I The SQL command completed successfully.  
DB20000I The SQL DISCONNECT command completed successfully.
```

**Notes**

Run this command as the root user.

A user specified in the -u option needs to have the privilege to run the SET WRITE command of DB2.

**Error Messages**

## 8.30 Controlling the rest point of MySQL (clpmysqlstill command)

Controls the rest point of MySQL.

### Command line

```
clpmysqlstill -d databasename [-u username] -s  
clpmysqlstill -d databasename -r
```

### Description

Controls the securing/release of the rest point of MySQL.

### Option

- d** *databasename*  
Specifies the name of the target database for rest point control.
- u** *username*  
Specifies the name of the database user who executes rest point control. This option can be specified only when the -s option is specified. If it is omitted, root is automatically set as a default user.
- s**  
Secures the rest point.
- r**  
Releases the rest point.

### Return Value

|    |                                                              |
|----|--------------------------------------------------------------|
| 0  | Normal completion                                            |
| 2  | Invalid command option                                       |
| 3  | DB connection error                                          |
| 4  | Authentication error for the user specified in the -u option |
| 5  | Failed to secure the rest point.                             |
| 6  | Failed to release the rest point.                            |
| 99 | Internal error                                               |

### Examples

```
# clpmysqlstill -d mysql -u root -s  
Command succeeded.  
  
# clpmysqlstill -d mysql -r  
Command succeeded.
```

### Notes

Run this command as the root user.

Configure a directory, where libmysqlclient.so client library of MySQL exists, to LD\_LIBRARY\_PATH, an environment variable.

Preliminarily configure the password of a user specified in the -u option, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the password. Put a colon ":" at the end of the row.

*"User name:Password:"*

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of password setting: root:password:

A user specified in the -u option needs to have privileges to execute FLUSH TABLES WITH READ LOCK statement of MySQL.

If the rest point has been secured by running the command for securing the rest point with the -s option, the control is not returned while the command remains resident. By running the command for releasing the rest point with the -r option at a different process, the resident command for securing the rest point finishes and the control is returned.

#### **Error Messages**

| Internal error.                      | An internal error has occurred.                                                           |

## 8.31 Controlling the rest point of Oracle (clporclstill command)

Controls the rest point of Oracle.

### Command line

```
clporclstill -d connectionstring [-u username] -s  
clporclstill -d connectionstring -r
```

### Description

Controls the securing/release of the rest point of Oracle.

### Option

- d** *connectionstring*  
Specifies the connection string for the target database for rest point control.
- u** *username*  
Specifies the name of a database user who executes rest point control. This option can be specified only when the -s option is specified. If it is omitted, OS authentication is used.
- s**  
Secures the rest point.
- r**  
Releases the rest point.

### Return Value

|    |                                   |
|----|-----------------------------------|
| 0  | Normal completion                 |
| 2  | Invalid command option            |
| 3  | DB connection error               |
| 4  | User authentication error         |
| 5  | Failed to secure the rest point.  |
| 6  | Failed to release the rest point. |
| 99 | Internal error                    |

### Examples

```
# clporclstill -d orcl -uoracle -s  
Command succeeded.  
  
# clporclstill -d orcl -r  
Command succeeded.
```

### Notes

Run this command as the root user.

Configure a directory, where libclntsh.so client library of Oracle exists, to LD\_LIBRARY\_PATH, an environment variable.

Additionally, configure the home directory of Oracle to ORACLE\_HOME, an environment variable.

If OS authentication is used without specifying the -u option, a user who runs this command needs to belong to the dba group, in order to gain administrative privileges for Oracle.

Preliminarily configure the password of a user specified in the -u option, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the password. Put a colon ":" at the end of the row.

*"User name:Password:"*

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of password setting: root:password:

A user specified in the -u option needs to have administrative privileges for Oracle.

If the rest point has been secured by running the command for securing the rest point with the -s option, the control is not returned while the command remains resident. By running the command for releasing the rest point with the -r option at a different process, the resident command for securing the rest point finishes and the control is returned.

Configure Oracle in the ARCHIVELOG mode in advance to run this command.

If an Oracle data file is acquired while this command is used to secure the rest point, the backup mode will be set for the data file. To restore and use the data file, disable the backup mode on Oracle to restore the data file.

### **Error Messages**

| Message                              | Cause/Solution                                                                            |
|--------------------------------------|-------------------------------------------------------------------------------------------|
| Invalid option.                      | Invalid command option.<br>Check the command option.                                      |
| Cannot connect to database.          | Failed to connect to the database.<br>Check the name and the status of the database.      |
| Username or password is not correct. | User authentication failed.<br>Check your user name and password.                         |
| Suspend database failed.             | Failed to secure the rest point.<br>Check the user privileges and the database settings.  |
| Resume database failed.              | Failed to release the rest point.<br>Check the user privileges and the database settings. |
| Internal error.                      | An internal error has occurred.                                                           |

## 8.32 Controlling the rest point of PostgreSQL (clppsqlstill command)

Controls the rest point of PostgreSQL.

### Command line

```
clppsqlstill -d databasename -u username -s  
clppsqlstill -d databasename -r
```

### Description

Controls the securing/release of the rest point of PostgreSQL.

### Option

**-d** *databasename*  
Specifies the name of the target database for rest point control.

**-u** *username*  
Specifies the name of the database user who executes rest point control.

**-s**  
Secures the rest point.

**-r**  
Releases the rest point.

### Return Value

|    |                                                              |
|----|--------------------------------------------------------------|
| 0  | Normal completion                                            |
| 2  | Invalid command option                                       |
| 3  | DB connection error                                          |
| 4  | Authentication error for the user specified in the -u option |
| 5  | Failed to secure the rest point.                             |
| 6  | Failed to release the rest point.                            |
| 99 | Internal error                                               |

### Examples

```
# clppsqlstill -d postgres -u postgres -s  
Command succeeded.  
  
# clppsqlstill -d postgres -r  
Command succeeded.
```

### Notes

Run this command as the root user.

Configure a directory, where libpq.so client library of PostgreSQL exists, to LD\_LIBRARY\_PATH, an environment variable.

If any number other than the default value (5432) is set to the port number connected to PostgreSQL, configure the port number in PQPORT, an environment variable.

Preliminarily configure the password of a user specified in the -u option, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the password. Put a colon ":" at the end of the row.

*"User name:Password:"*

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of password setting: root:password:

A user specified in the -u option needs to have superuser privileges for PostgreSQL.

Enable WAL archive of PostgreSQL in advance to run this command.

If the rest point has been secured by running the command for securing the rest point with the -s option, the control is not returned while the command remains resident. By running the command for releasing the rest point with the -r option at a different process, the resident command for securing the rest point finishes and the control is returned.

#### **Error Messages**

| Message                              | Cause/Solution                                                                            |
|--------------------------------------|-------------------------------------------------------------------------------------------|
| Invalid option.                      | Invalid command option.<br>Check the command option.                                      |
| Cannot connect to database.          | Failed to connect to the database.<br>Check the name and the status of the database.      |
| Username or password is not correct. | User authentication failed.<br>Check your user name and password.                         |
| Suspend database failed.             | Failed to secure the rest point.<br>Check the user privileges and the database settings.  |
| Resume database failed.              | Failed to release the rest point.<br>Check the user privileges and the database settings. |
| Internal error.                      | An internal error has occurred.                                                           |

## 8.33 Controlling the rest point of SQL Server (clpmssqlstill command)

Controls the rest point of SQL Server.

### Command line

```
clpmssqlstill -d databasename -u username -v vdusername -s  
clpmssqlstill -d databasename -v vdusername -r
```

### Description

Controls the securing/release of the rest point of SQL Server.

### Option

- d** *databasename*  
Specifies the name of the target database for rest point control.
- u** *username*  
Specifies the name of the database user who executes rest point control.
- v** *vdusername*  
Specifies the name of an OS user who executes vdi
- s**  
Secures the rest point.
- r**  
Releases the rest point.

### Return Value

|    |                                                              |
|----|--------------------------------------------------------------|
| 0  | Normal completion                                            |
| 2  | Invalid command option                                       |
| 3  | DB connection error                                          |
| 4  | Authentication error for the user specified in the -u option |
| 5  | Failed to secure the rest point.                             |
| 6  | Failed to release the rest point.                            |
| 7  | Timeout error                                                |
| 99 | Internal error                                               |

### Examples

```
# clpmssqlstill -d userdb -u sa -v mssql -s  
Command succeeded.  
  
# clpmssqlstill -d userdb -v mssql -r  
Command succeeded.
```

### Notes

Run this command as the root user.

Configure directories, where libsqlvdi.so VDI client library of SQL Server and libodbc.so ODBC library exist, to LD\_LIBRARY\_PATH, an environment variable.

Preliminarily configure the password of a user specified in the -u option, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the password. Put a colon

":" at the end of the row.

*"User name:Password:"*

Example of file path: **/opt/nec/clusterpro/etc/stillpoint.conf**

Example of password setting: **sa:password:**

A user specified in the -u option needs to have privileges to execute the BACKUP DATABASE statement of SQL Server.

An OS user specified in the -v option needs to have privileges to execute VDI client.

You need to preliminarily configure the timeout value of this command in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the timeout time. Put a colon ":" at the last row. Unless it is set, the value described in the following example will be used as the default value.

*"Timeout name: number of seconds:"*

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of time-out (GetConfiguration) configured: cfgtimeout:1:

Example of time-out (GetCommand) configured: cmdtimeout:90:

Example of time-out (SQL) configured: sqltimeout:60:

You need to preliminarily configure the ODBC driver used for operating the database, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the ODBC driver. Put a colon ":" at the end of the row. Unless it is set, the value described in the following example is used as the default value.

*"ODBC driver: Name of ODBC driver to be used:"*

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of ODBC driver: odbcdriver:ODBC Driver 13 for SQL Server:

If the rest point has been secured by running the command for securing the rest point with the -s option, the control is not returned while the command remains resident. By running the command for releasing the rest point with the -r option at a different process, the resident command for securing the rest point finishes and the control is returned.

## **Error Messages**

| Message                              | Cause/Solution                                                                       |
|--------------------------------------|--------------------------------------------------------------------------------------|
| Invalid option.                      | Invalid command option.<br>Check the command option.                                 |
| Cannot connect to database.          | Failed to connect to the database.<br>Check the name and the status of the database. |
| Username or password is not correct. | User authentication failed.<br>Check your user name and password.                    |

| Timeout.                 | The command timed out.                                                                    |
| Internal error.          | An internal error has occurred.                                                           |

## 8.34 Controlling the rest point of Sybase (clpsybasestill command)

Controls the rest point of Sybase.

### Command line

```
clpsybasestill -d databasename -u username -s  
clpsybasestill -d databasename -r
```

### Description

Controls the securing/release of the rest point of Sybase.

### Option

**-d** *databasename*  
Specifies the name of the target database for rest point control.

**-u** *username*  
Specifies the name of the database user who executes rest point control.

**-s**  
Secures the rest point.

**-r**  
Releases the rest point.

### Return Value

|    |                                                              |
|----|--------------------------------------------------------------|
| 0  | Normal completion                                            |
| 2  | Invalid command option                                       |
| 3  | DB connection error                                          |
| 4  | Authentication error for the user specified in the -u option |
| 5  | Failed to secure the rest point.                             |
| 6  | Failed to release the rest point.                            |
| 99 | Internal error                                               |

### Examples

```
# clpsybasestill -d master -u sa -s  
Command succeeded.  
  
# clpsybasestill -d master -r  
Command succeeded.
```

### Notes

Run this command as the root user. Configure a directory, where libsybdb64.so client library of Sybase exists, to LD\_LIBRARY\_PATH, an environment variable. Additionally, configure appropriate settings for the following environment variables.

SYBASE: Install directory of Sybase.

LANG: Languages which the installed Sybase can accommodate.

DSQUERY: Database server name of Sysbase.

Preliminarily configure the password of a user specified in the -u option, in the stillpoint.conf file of the etc directory under EXPRESSCLUSTER install directory. Use the following format for the password. Put a colon ":" at the end of the row.

"User name:Password:"

Example of file path: /opt/nec/clusterpro/etc/stillpoint.conf

Example of password setting: root:password:

A user specified in the -u option needs to have privileges to execute the quiesce database command of Sybase.

If the rest point has been secured by running the command for securing the rest point with the -s option, the control is not returned while the command remains resident. By running the command for releasing the rest point with the -r option at a different process, the resident command for securing the rest point finishes and the control is returned.

#### Error Messages

| Message                              | Cause/Solution                                                                            |
|--------------------------------------|-------------------------------------------------------------------------------------------|
| Invalid option.                      | Invalid command option.<br>Check the command option.                                      |
| Cannot connect to database.          | Failed to connect to the database.<br>Check the name and the status of the database.      |
| Username or password is not correct. | User authentication failed.<br>Check your user name and password.                         |
| Suspend database failed.             | Failed to secure the rest point.<br>Check the user privileges and the database settings.  |
| Resume database failed.              | Failed to release the rest point.<br>Check the user privileges and the database settings. |
| Internal error.                      | An internal error has occurred.                                                           |

## 8.35 Displaying the cluster statistics information (clpperfc command)

the clpperfc command displays the cluster statistics information.

### Command line

```
clpperfc --starttime -g group_name
clpperfc --stoptime -g group_name
clpperfc -g [group_name]
clpperfc -m monitor_name
```

### Description

This command displays the median values (millisecond) of the group start time and group stop time.

This command displays the monitoring processing time (millisecond) of the monitor resource.

### Option

**--starttime** -g *group\_name*  
Displays the median value of the group start time.

**--stoptime** -g *group\_name*  
Displays the median value of the group stop time.

**-g** [*group\_name*]  
Displays the each median value of the group start time and group stop time.  
If groupname is omitted, it displays the each median value of the start time and stop time of all the groups.

**-m** *monitor\_name*  
Displays the last monitor processing time of the monitor resource.

### Return value

|    |                                             |
|----|---------------------------------------------|
| 0  | Normal termination                          |
| 1  | Invalid command option                      |
| 2  | User authentication error                   |
| 3  | Configuration information load error        |
| 4  | Configuration information load error        |
| 5  | Initialization error                        |
| 6  | Internal error                              |
| 7  | Internal communication initialization error |
| 8  | Internal communication connection error     |
| 9  | Internal communication processing error     |
| 10 | Target group check error                    |
| 12 | Timeout error                               |

### Example of Execution

When displaying the median value of the group start time:

```
# clpperfc --starttime -g failover1
200
```

When displaying each median value of the start time and stop time of the specific group:

```
# clpperfc -g failover1
               start time    stop time
failover1      200           150
```

When displaying the monitor processing time of the monitor resource:

```
# clpperfc -m monitor1  
100
```

**Remarks**

The time is output in millisecond by this commands.

If the valid start time or stop time of the group was not obtained, - is displayed.

If the valid monitoring time of the monitor resource was not obtained, 0 is displayed.

**Notes**

Execute this command as a root user.

**Error Messages**

| Message          | Cause/Solution                                           |

## 8.36 Checking the cluster configuration information (clpcfchk command)

This command checks the cluster configuration information.

### Command line

```
clpcfchk -o path [-i conf_path]
```

### Description

This command checks the validness of the setting values based on the cluster configuration information.

### Option

- o** *path*  
Specifies the directory to store the check results.
- i** *conf\_path*  
Specifies the directory which stored the configuration information to check.  
If this option is omitted, the applied configuration information is checked.

### Return Value

|       |                                  |
|-------|----------------------------------|
| 0     | Normal termination               |
| Other | than 0 Termination with an error |

### Example of Execution

When checking the applied configuration information:

```
# clpcfchk -o /tmp
server1 : PASS
server2 : PASS
```

When checking the stored configuration information:

```
# clpcfchk -o /tmp -i /tmp/config
server1 : PASS
server2 : FAIL
```

### Execution Result

For this command, the following check results (total results) are displayed.

| Check Results (Total Results) | Description                                 |
|-------------------------------|---------------------------------------------|
| PASS                          | No error found.                             |
| FAIL                          | An error found.<br>Check the check results. |

### Remarks

Only the total results of each server are displayed.

### Notes

Run this command as a root user.

When checking the configuration information exported through Cluster WebUI, decompress it in advance.

**Error Messages**

| Message                                                                                                | Cause/Solution                                                                         |
|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Log in as root.                                                                                        | Log in as a root user.                                                                 |
| Invalid option.                                                                                        | Specify a valid option.                                                                |
| Could not opened the configuration file. Check if the configuration file exists on the specified path. | The specified path does not exist. Specify a valid path.                               |
| Server is busy. Check if this command is already run.                                                  | This command has been already activated.                                               |

| Failed to check validation.                                                                            | Failed to check the cluster configuration.                                             |
| Internal error. Check if memory or OS resources are sufficient.                                        | The amount of memory or OS resources may be insufficient. Check for any insufficiency. |

## 8.37 Creating a cluster configuration data file (clpcfset command)

Creates a cluster configuration data file.

### Command line

```
clpcfset {create|--create} clustername charset [encode]  
clpcfset {add|--add} clsparam tagname parameter  
clpcfset {add|--add} srv servername priority  
clpcfset {add|--add} device servername type id info [extend]  
clpcfset {add|--add} hb lankhb deviceid priority  
clpcfset {add|--add} hb lanhb deviceid priority  
clpcfset {add|--add} hb diskhb deviceid priority  
clpcfset {add|--add} hb witnesshb deviceid priority host  
clpcfset {add|--add} np pingnp deviceid priority groupid listid ipadress  
clpcfset {add|--add} np httpnp deviceid priority [host]  
clpcfset {add|--add} grp grouptype groupname  
clpcfset {add|--add} grpparam groupname tagname parameter  
clpcfset {add|--add} rsc groupname resourcetype resourcename  
clpcfset {add|--add} rscparam resourcetype resourcename tagname parameter  
clpcfset {add|--add} rscdep resourcetype resourcename dependresourcename  
clpcfset {add|--add} mon monitortype resourcename  
clpcfset {add|--add} monparam monitortype resourcename tagname parameter
```

### Description

Creates a cluster configuration data file to be outputted to a file.

### Option

**{create|--create}** *clustername charset encode*  
Specifies a cluster name and an encoding to create a new cluster.

For *clustername*, specify a cluster name. For *charset*, depending on the language used in EXPRESSCLUSTER, specify EUC-JP for Japanese, ASCII for English, and GB2312 for Chinese, respectively.

*encode* is a parameter to be determined by the OS for a server where WebUI operates and the language used in EXPRESSCLUSTER, in creating the configuration data in WebUI. When omitted, the settings are the same as those for *charset*.

OS is Windows: SJIS

OS is Linux and in Japanese: EUC-JP

OS is Linux and in English: ASCII

OS is Linux and in Chinese: GB2312

**{add|--add}** *<param>*  
*param*

**clsparam tagname parameter**

Specifies a tag name and parameters of a cluster to set its properties.

For information on *tagname* or *parameter*, see "[Parameters list \(clpcfset command\)](#)".

**srv servername priority**

Specifies a server name and its priority to add the server.

Specify a server name as `servername`.

The priority number for the master server is 0. For other servers, the priority number is incremented by one.

**device `servername` type id info [extend]**

Specifies a server name and its type to add a device.

Specify type from `lan`, `mdc`, `disk`, `witness`, `ping`, or `http`.

`id` starts with 0, being incremented by one.

If `lan` or `mdc` is specified as type, specify the IP address as `info`.

If `disk` is specified as type, specify the path to the device as `info`.

If `witness` is specified as type, specify 0 (not used) or 1 (used) as `info`, and specify the host address and the port (`address:port`) of the witness server to be connected to, as `extend`.

If `ping`, `http`, or `majo` is specified as type, specify 0 (not used) or 1 (used) as `info`.

**hb `lankhb` deviceid priority**

Specifies the device ID and priority to add a kernel mode heartbeat.

For `deviceid`, use the ID specified by "add device".

priority of the heartbeat starts with 0, being incremented by one.

**hb `lanhb` deviceid priority**

Specifies the device ID and the priority to add a user-mode heartbeat.

For `deviceid`, use the ID specified by "add device".

priority of the heartbeat starts with 0, being incremented by one.

**hb `diskhb` deviceid priority**

Specifies the device ID and the priority to add a disk heartbeat.

For `deviceid`, use the ID specified by "add device".

priority of the heartbeat starts with 0, being incremented by one.

**hb `witnesshb` deviceid priority host**

Specifies the device ID, priority, and target host to add a witness heartbeat.

For `deviceid`, use the ID specified by "add device".

priority of the heartbeat starts with 0, being incremented by one.

For `host`, specify the host address and the port (`address:port`) of the witness server to be connected to.

**np `pingnp` deviceid priority groupid listid ipadress**

Specifies the priority, device ID, group ID, list ID, and IP address to add the PING NP resolution resource.

For `deviceid`, use the ID specified by "add device".

priority, groupid, and listid start with 0, being incremented by one.

For `ipadress`, specify the IP address to be used for the NP resolution resource.

**np `httpnp` priority deviceid [host]**

Specifies the device ID, priority, and target host to add the HTTP NP resolution resource.

For `deviceid`, use the ID specified by "add device".

priority of the NP resolution resource starts with 0, being incremented by one.

For `[host]`, specify the host address and the port (`address:port`) of the witness server to be connected to.

When [host] is omitted, use the settings of the witness HB resource.

#### **grp grouptype groupname**

Specifies a group type and group name to add the group.

For grouptype, specify failover or virtualmachine.

#### **grpparam groupname tagname parameter**

Specifies a group name, tag name, and parameters to set the properties of the group.

For information on tagname or parameter, see "[Parameters list \(clpcfset command\)](#)".

#### **rsc groupname resourcetype resourcename**

Specifies a group name, resource type, and resource name to add the resource.

#### **rscparam resourcetype resourcename tagname paramter**

Specifies a resource type, resource name, tag name, and parameters to set the properties of the resource.

For information on tagname or parameter, see "[Parameters list \(clpcfset command\)](#)".

#### **rscdep resourcetype resourcename dependresourcename**

Specifies a resource name to add the dependencies of the resource.

Specify a resource type and resource name as resourcetype and resourcename, respectively, and specify a dependent resource as dependresourcename.

If the dependencies are set for the group resource, the group resource (i.e., resourcename) starts to activate after completing the activation of dependresourcename, and dependresourcename starts to deactivate after completing the deactivation of the group resource (i.e., resourcename).

The following shows an example of the dependencies for the resources belonging to the corresponding group:

| Group Properties   failover1                                                     |       |                         |                      |
|----------------------------------------------------------------------------------|-------|-------------------------|----------------------|
| failover X                                                                       |       |                         |                      |
| Info Startup Server Attribute Start Dependency Stop Dependency Entire Dependency |       |                         |                      |
| Depth                                                                            | Name  | Dependent Resource Name | Type                 |
| 0                                                                                | fip1  | none                    |                      |
| 1                                                                                | disk1 | fip1                    | Floating IP resource |
| 2                                                                                | exec1 | disk1                   | Disk resource        |
|                                                                                  |       | fip1                    | Floating IP resource |
| OK Cancel Apply                                                                  |       |                         |                      |

Fig. 8.11: Activation order

Fig. 8.12: Deactivation order

**mon monitortype monitorresource**

Specifies a monitor resource type and monitor resource name to add the monitor resource.

**monparam monitortype monitorresource tagname paramter**

Specifies a monitor resource type, monitor resource name, tag name, and parameters to set the properties of the monitor resource.

For information on tagname or parameter, see "*Parameters list (clpcfset command)*".

**Return value**

|              |         |
|--------------|---------|
| 0            | Success |
| Other than 0 | Failure |

**Notes**

Run this command as a root user.

For information on input-enabled or forbidden character strings for each parameter, see "*EXPRESSCLUSTER X 4.3 for Linux Reference Guide*".

This command creates only clp.conf among the cluster configuration data files. The script files for a script resource/EXE resource or customized monitor resource must be created manually.

**Example** Placing the scripts for the script resource of script1 belonging to the failover group of failover1, and the scripts for the customized monitor resource of genw1:

```

scripts
  +--failover1
  |   +--exec1
  |       start.sh
  |       stop.sh
  |
  +--monitor.s
      +--genw1
          genw.sh
  
```

Use xmlint for formatting the clp.conf created with this command. Depending on the environment, xmlint needs to be installed.

The following shows an example of formatting an XML document to be outputted to a file:

```

xmlint --format --output <File path of formatted clp.conf> <File path of clp.
↪conf not yet formatted>
  
```

**Example of Execution**

Adding a cluster:

```

# clpcfset create cluster ASCII SJIS
# clpcfset add clsparm pm/exec0/recover 7
  
```

```
# clpcfset add clsparam pm/exec1/recover 7
# clpcfset add clsparam pm/exec2/recover 7
Adding a server:
# clpcfset add srv server1 0
Adding a kernel heartbeat:
# clpcfset add device server1 lan 0 192.168.137.71
# clpcfset add hb lankhb 0 0
Adding a user-mode heartbeat:
# clpcfset add device server1 lan 0 192.168.138.71
# clpcfset add hb lanhb 1 1
Adding a disk heartbeat:
# clpcfset add device server1 disk 0 /dev/sdc1
# clpcfset add hb diskhb 0 2
Adding a Witness heartbeat:
# clpcfset add device server1 witness 0 1 192.168.2.1:49152
# clpcfset add hb witnesshb 0 3 192.168.2.1:49152
Adding the PING network partition resolution resource:
# clpcfset add device server1 ping 0 1
# clpcfset add np pingnp 0 1 0 0 192.168.1.1
Adding the HTTP NP resolution resource:

Using the settings of the Witness HB resource:
# clpcfset add device server1 http 0 1
# clpcfset add np httpnp 0 2
Not using the settings of the Witness HB resource
# clpcfset add device server1 http 0 1
# clpcfset add np httpnp 0 2 192.168.2.2:49152
Adding a group:
# clpcfset add grp failover failover1
# clpcfset add grpparam failover1 policy@server1/order 0
# clpcfset add grpparam failover1 policy@server2/order 1
Adding a resource:
# clpcfset add rsc failover1 fip fip1
# clpcfset add rscparam fip fip1 parameters/ip 192.168.137.171
Adding the dependencies of resources:
# clpcfset add rscdep exec exec1 disk1
Adding a monitor resource:
# clpcfset add mon diskw diskw1
# clpcfset add monparam diskw diskw1 parameters/object /dev/sdc1
```

## **Error Messages**
