BACKGROUND

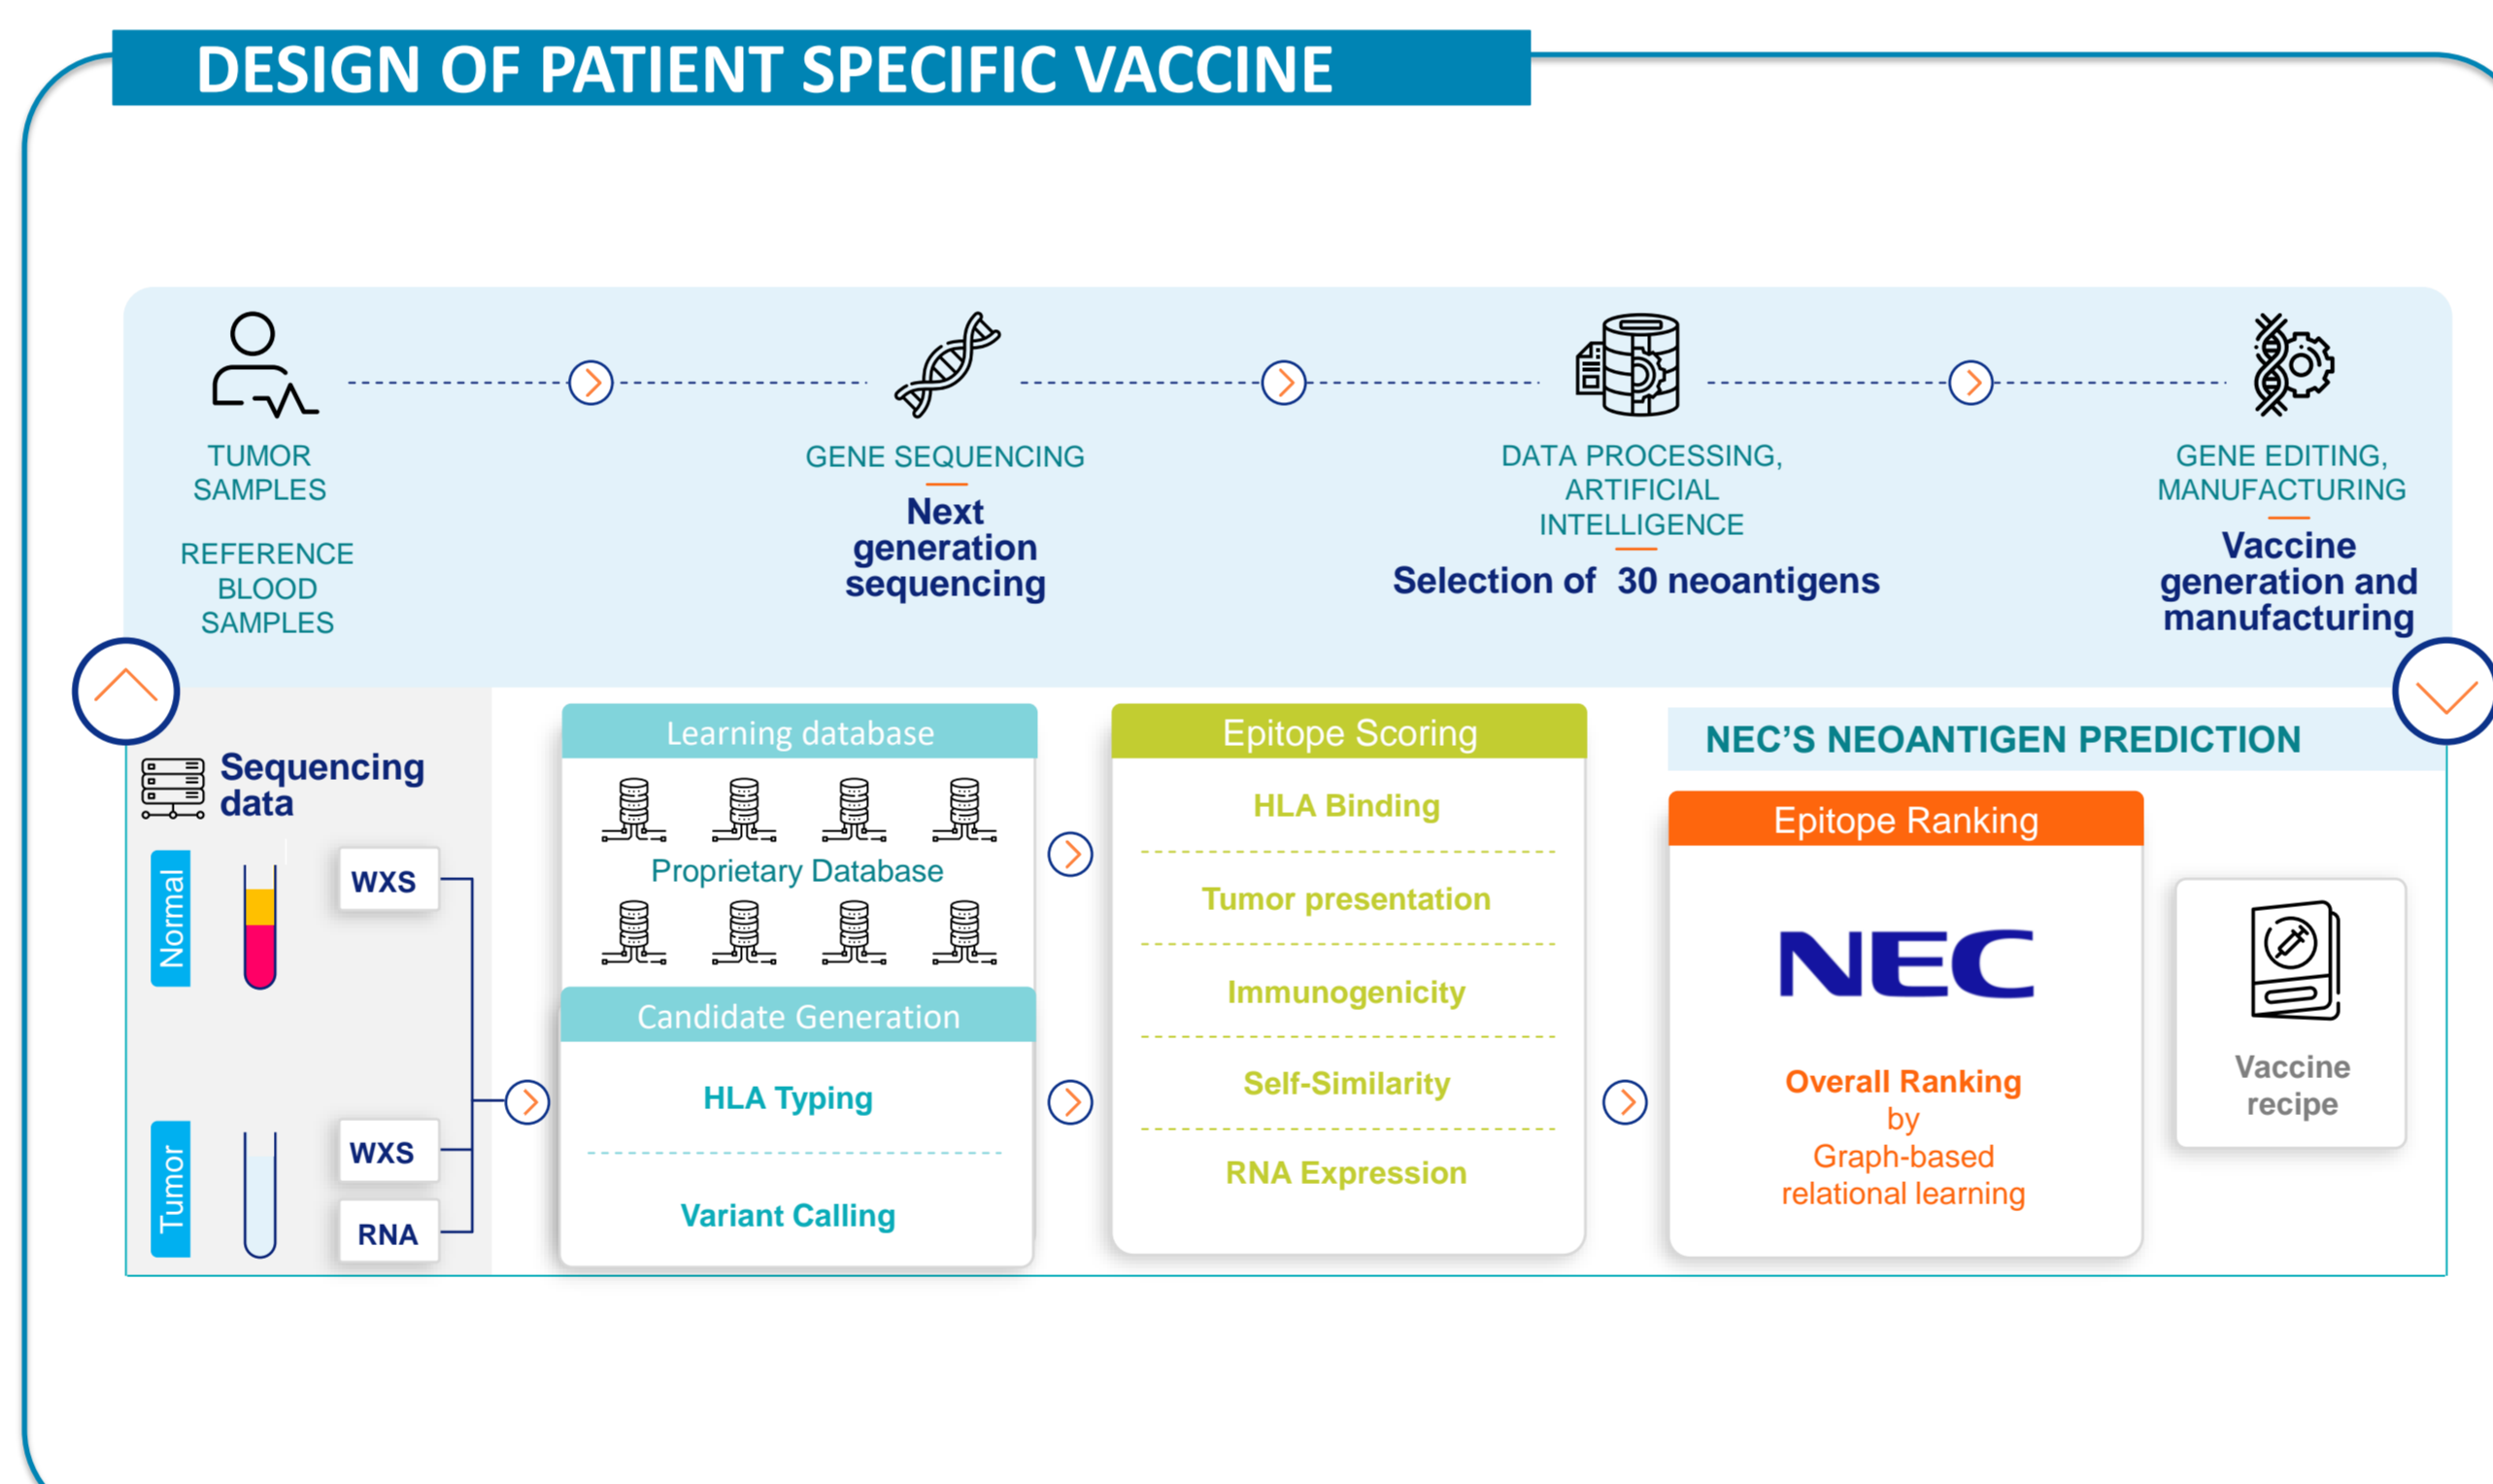

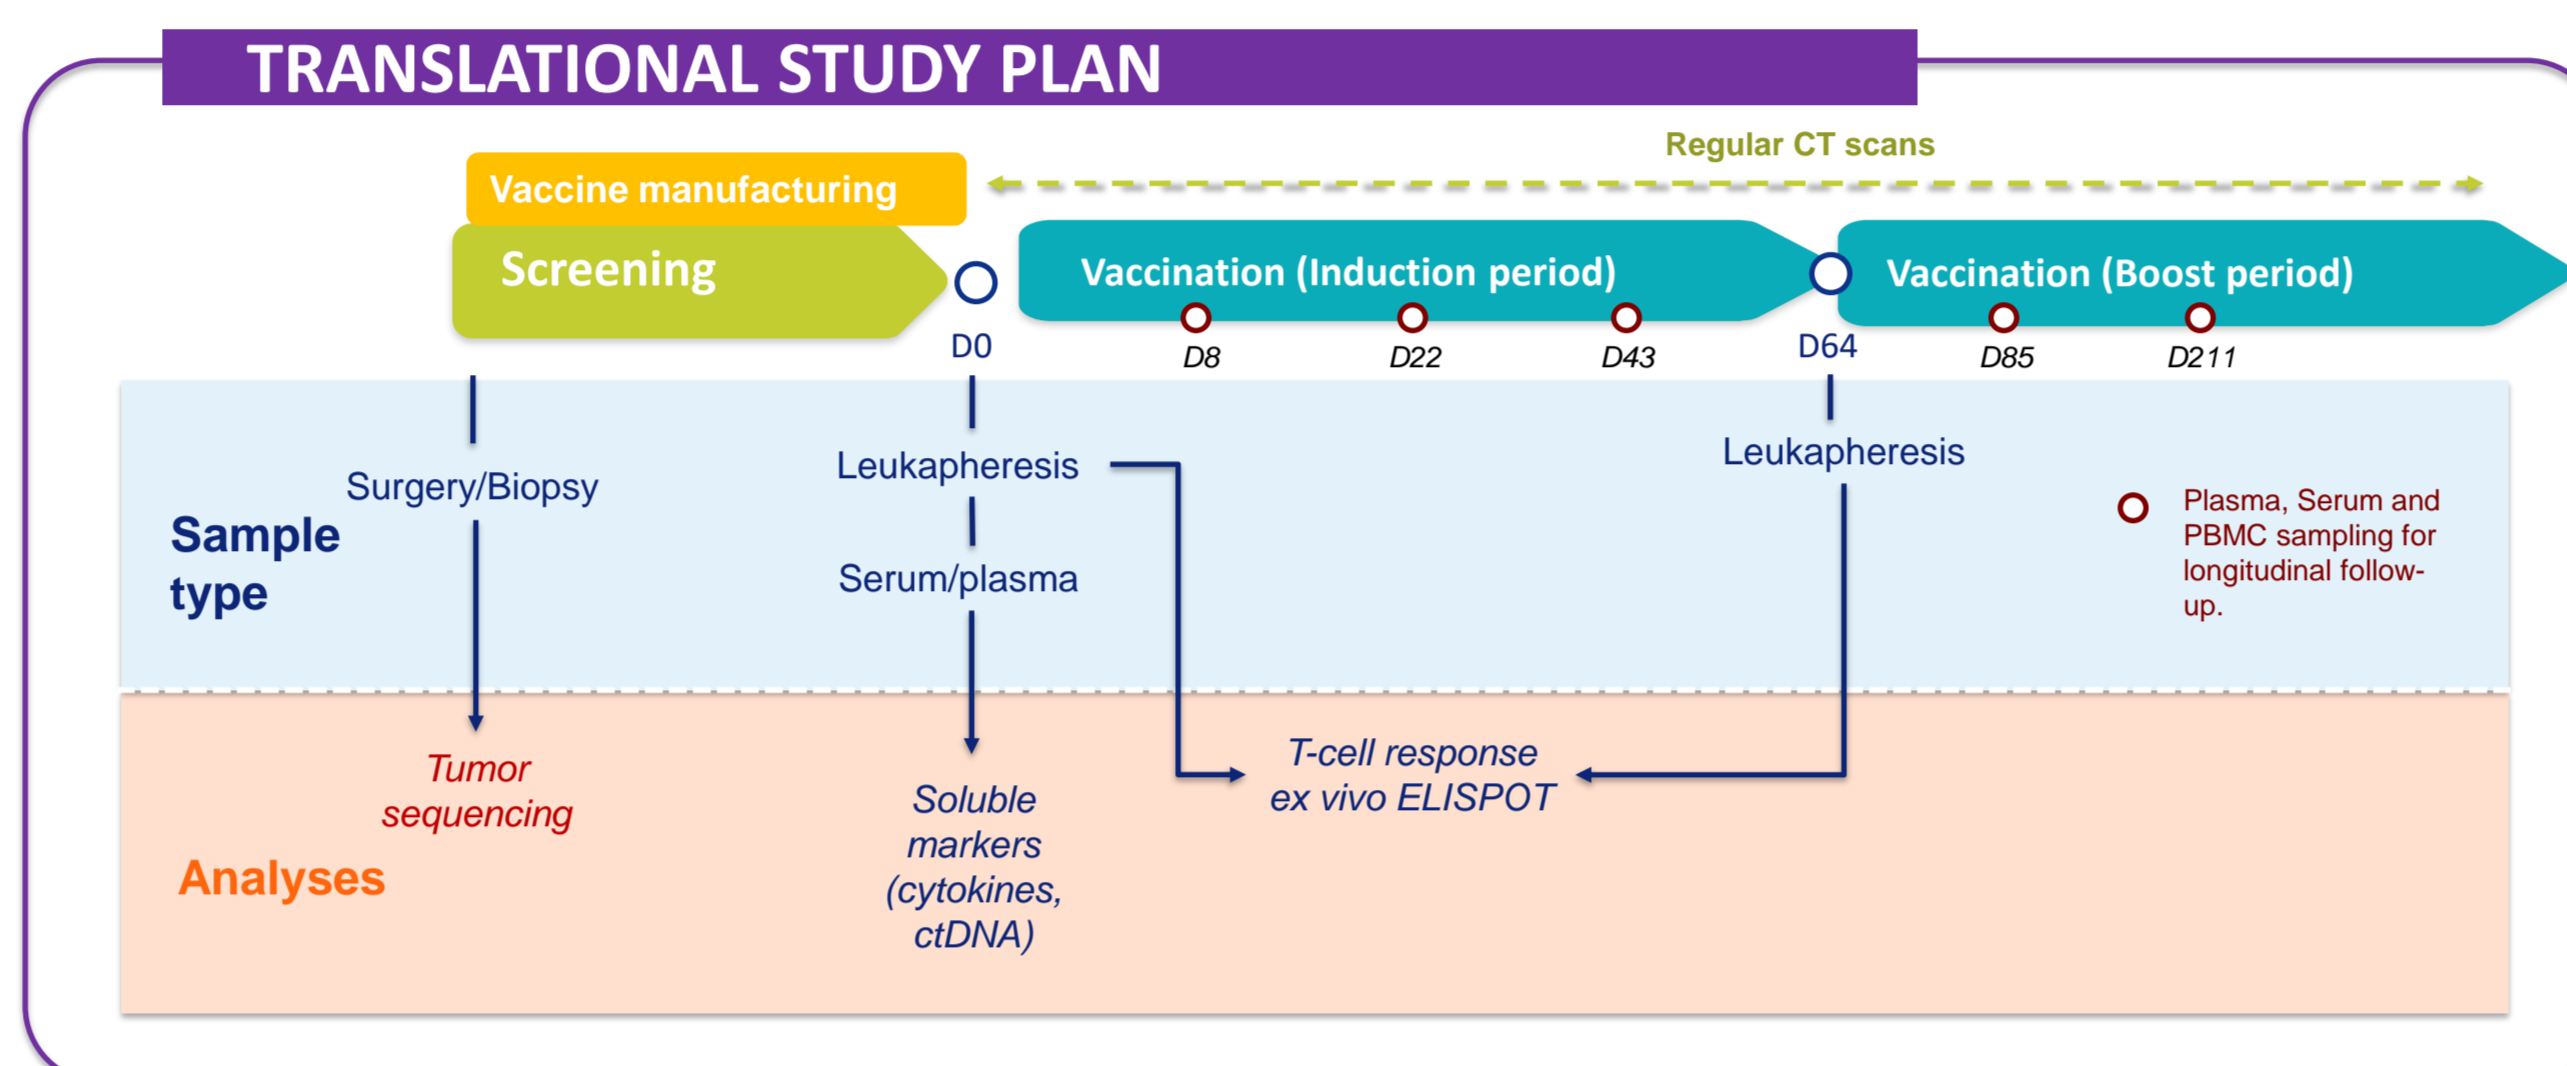

Cancer mutations acquired during carcinogenesis are not subject to central tolerance and thus are immunologically attractive targets for vaccination. The use of mutation-derived neopeptides to design cancer vaccines is an unprecedented opportunity to target efficient antigens, but the stochastic occurrence of mutations implies that a tailored vaccine needs to be designed and manufactured for each patient. We used next generation sequencing, machine learning based genomic data analysis and advances in genome editing to systematically identify private neopeptides in high-risk HPV negative HNSCC and relapsing OvC patients.

METHODS

Mutations were identified by DNA and RNA sequencing and putative epitopes were selected for vaccine design based on their likelihood to elicit a class I or II response using data on HLA binding, allelic frequency, prediction of processing and expression at RNA level. The vaccine was a recombinant virus of the modified Vaccinia Ankara (MVA) strain encoding for up to 30 sequences of 29 amino acids, centered on the predicted epitopes and flanked with the normal germline sequence in case of missense mutations, and of the mutated protein sequence in case of frameshift mutations. The viral vaccine was amplified under GMP conditions and administered to patients after completion of SOC treatment given with curative intent in two phase I trials. Monotherapy with the vaccine was started for OvC patients at relapse defined as elevation of CA-125 or onset of suspicious radiological findings and for locally advanced HNSCC patients following upfront surgery and adjuvant therapy. Head and Neck patients were randomized to receive the vaccine immediately after first line treatment in monotherapy (Arm A) or at relapse (Arm B) in conjunction with standard of care. In both studies, the vaccine was administered weekly for 6 weeks and a booster dose every three weeks over a year.

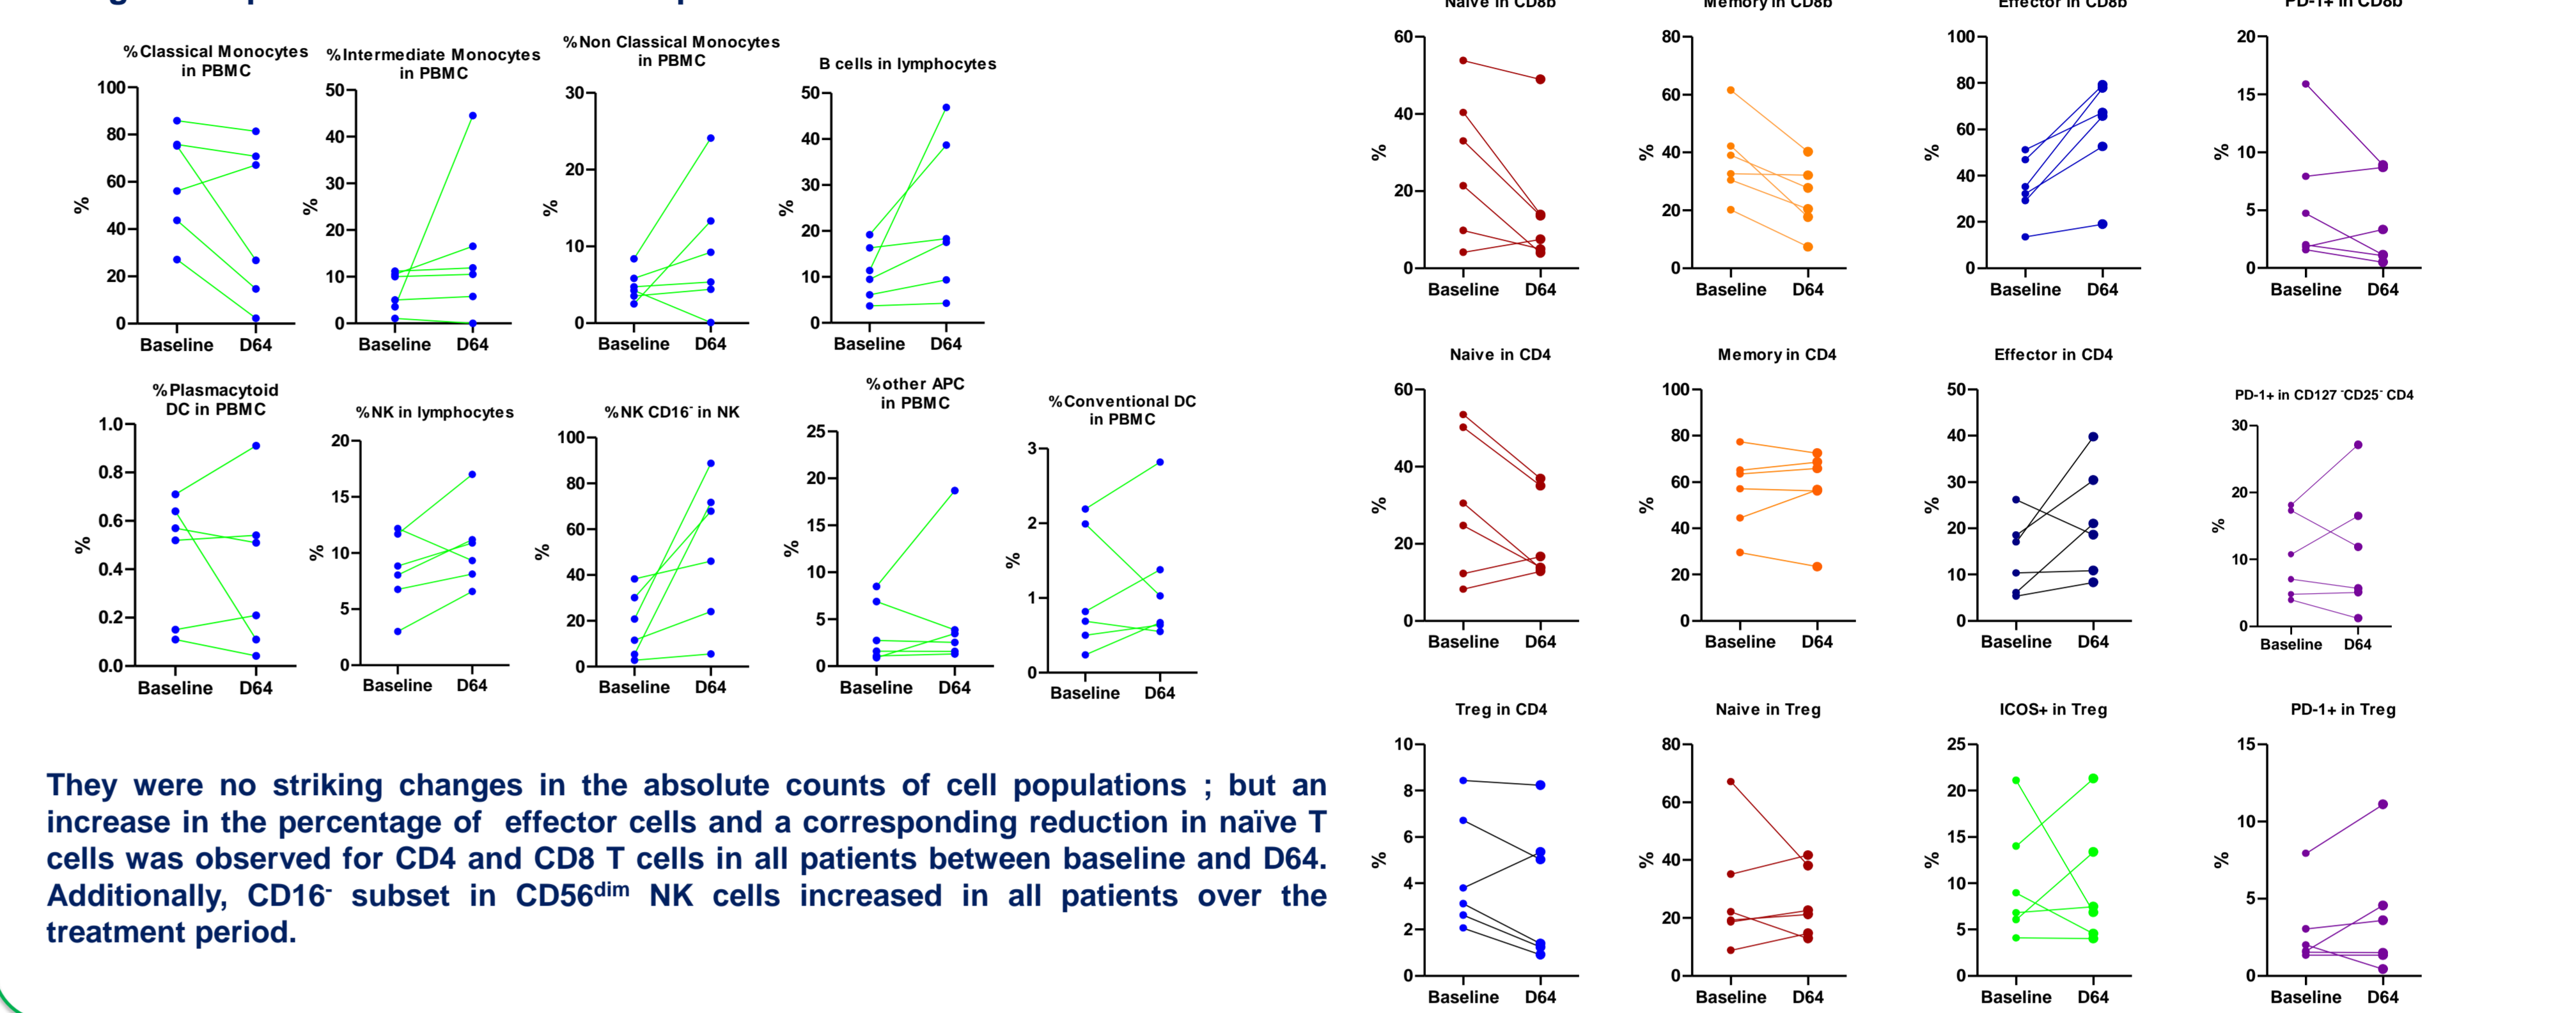

STUDY POPULATION

Ovarian cancer patients		HNSCC patients	
Key Inclusion Criteria	<ul style="list-style-type: none"> Stage IIIc or stage IVA (FIGO staging) high grade serous ovarian, fallopian or primary peritoneal carcinoma Complete response maintained at least 6 months after debulking surgery and first-line chemotherapy Asymptomatic relapse (elevated CA-125 or radiological findings) ECOG Performance status 0 or 1 	<ul style="list-style-type: none"> Newly diagnosed stage III or IVA squamous-cell carcinoma of the oral cavity, oropharynx, hypopharynx or larynx eligible for gross total resection and adjuvant therapy Complete response 3 months after completion of adjuvant therapy ECOG Performance status 0 or 1 	<ul style="list-style-type: none"> HPV-positive oropharynx primaries, carcinoma of the nasopharynx, squamous cell-carcinoma of unknown primary, squamous cell carcinoma that originates from the skin and salivary gland or paranasal sinus, non-squamous histologies Prior exposure to cancer immunotherapy including anti-cancer vaccines, any antibody targeting T cell co-regulatory proteins such as anti-PD L1, anti-PD 1, or anti-CTLA-4 antibodies Chronic treatment with systemic corticosteroids
Key Exclusion Criteria	<ul style="list-style-type: none"> Prior exposure to cancer immunotherapy including anti-cancer vaccines, any antibody targeting T cell co-regulatory proteins such as anti-PD L1, anti-PD 1, or anti-CTLA-4 antibodies Chronic treatment with systemic corticosteroids 	<ul style="list-style-type: none"> HPV-positive oropharynx primaries, carcinoma of the nasopharynx, squamous cell-carcinoma of unknown primary, squamous cell carcinoma that originates from the skin and salivary gland or paranasal sinus, non-squamous histologies Prior exposure to cancer immunotherapy including anti-cancer vaccines, any antibody targeting T cell co-regulatory proteins such as anti-PD L1, anti-PD 1, or anti-CTLA-4 antibodies Chronic treatment with systemic corticosteroids 	

PHENOTYPING OF CIRCULATING CELLS

PBMC were analysed by flow cytometry to quantify relevant immune cell subpopulations, in particular monocytes, DC, NK cells, subcells of CD8, CD4, Treg and expression of immune checkpoints ICOS and PD1.

They were no striking changes in the absolute counts of cell populations; but an increase in the percentage of effector cells and a corresponding reduction in naive T cells was observed for CD4 and CD8 T cells in all patients between baseline and D64. Additionally, CD16^{dim} subset in CD56^{dim} NK cells increased in all patients over the treatment period.

ADAPTIVE T-CELL RESPONSES BY EX VIVO ELISPOTS IFN γ

Data on antigen specific T cell responses were available from 4 patients at the time of the present publication, specifically OvC patients 1 and 3 and HNSCC patients 1 and 2. PBMCs were restimulated using 15-mers encoding for the mutations targeted by the vaccine. Response against each vaccine target were tested individually.

OBJECTIVE CLINICAL RESPONSE IN PATIENT 1 OF OVc STUDY

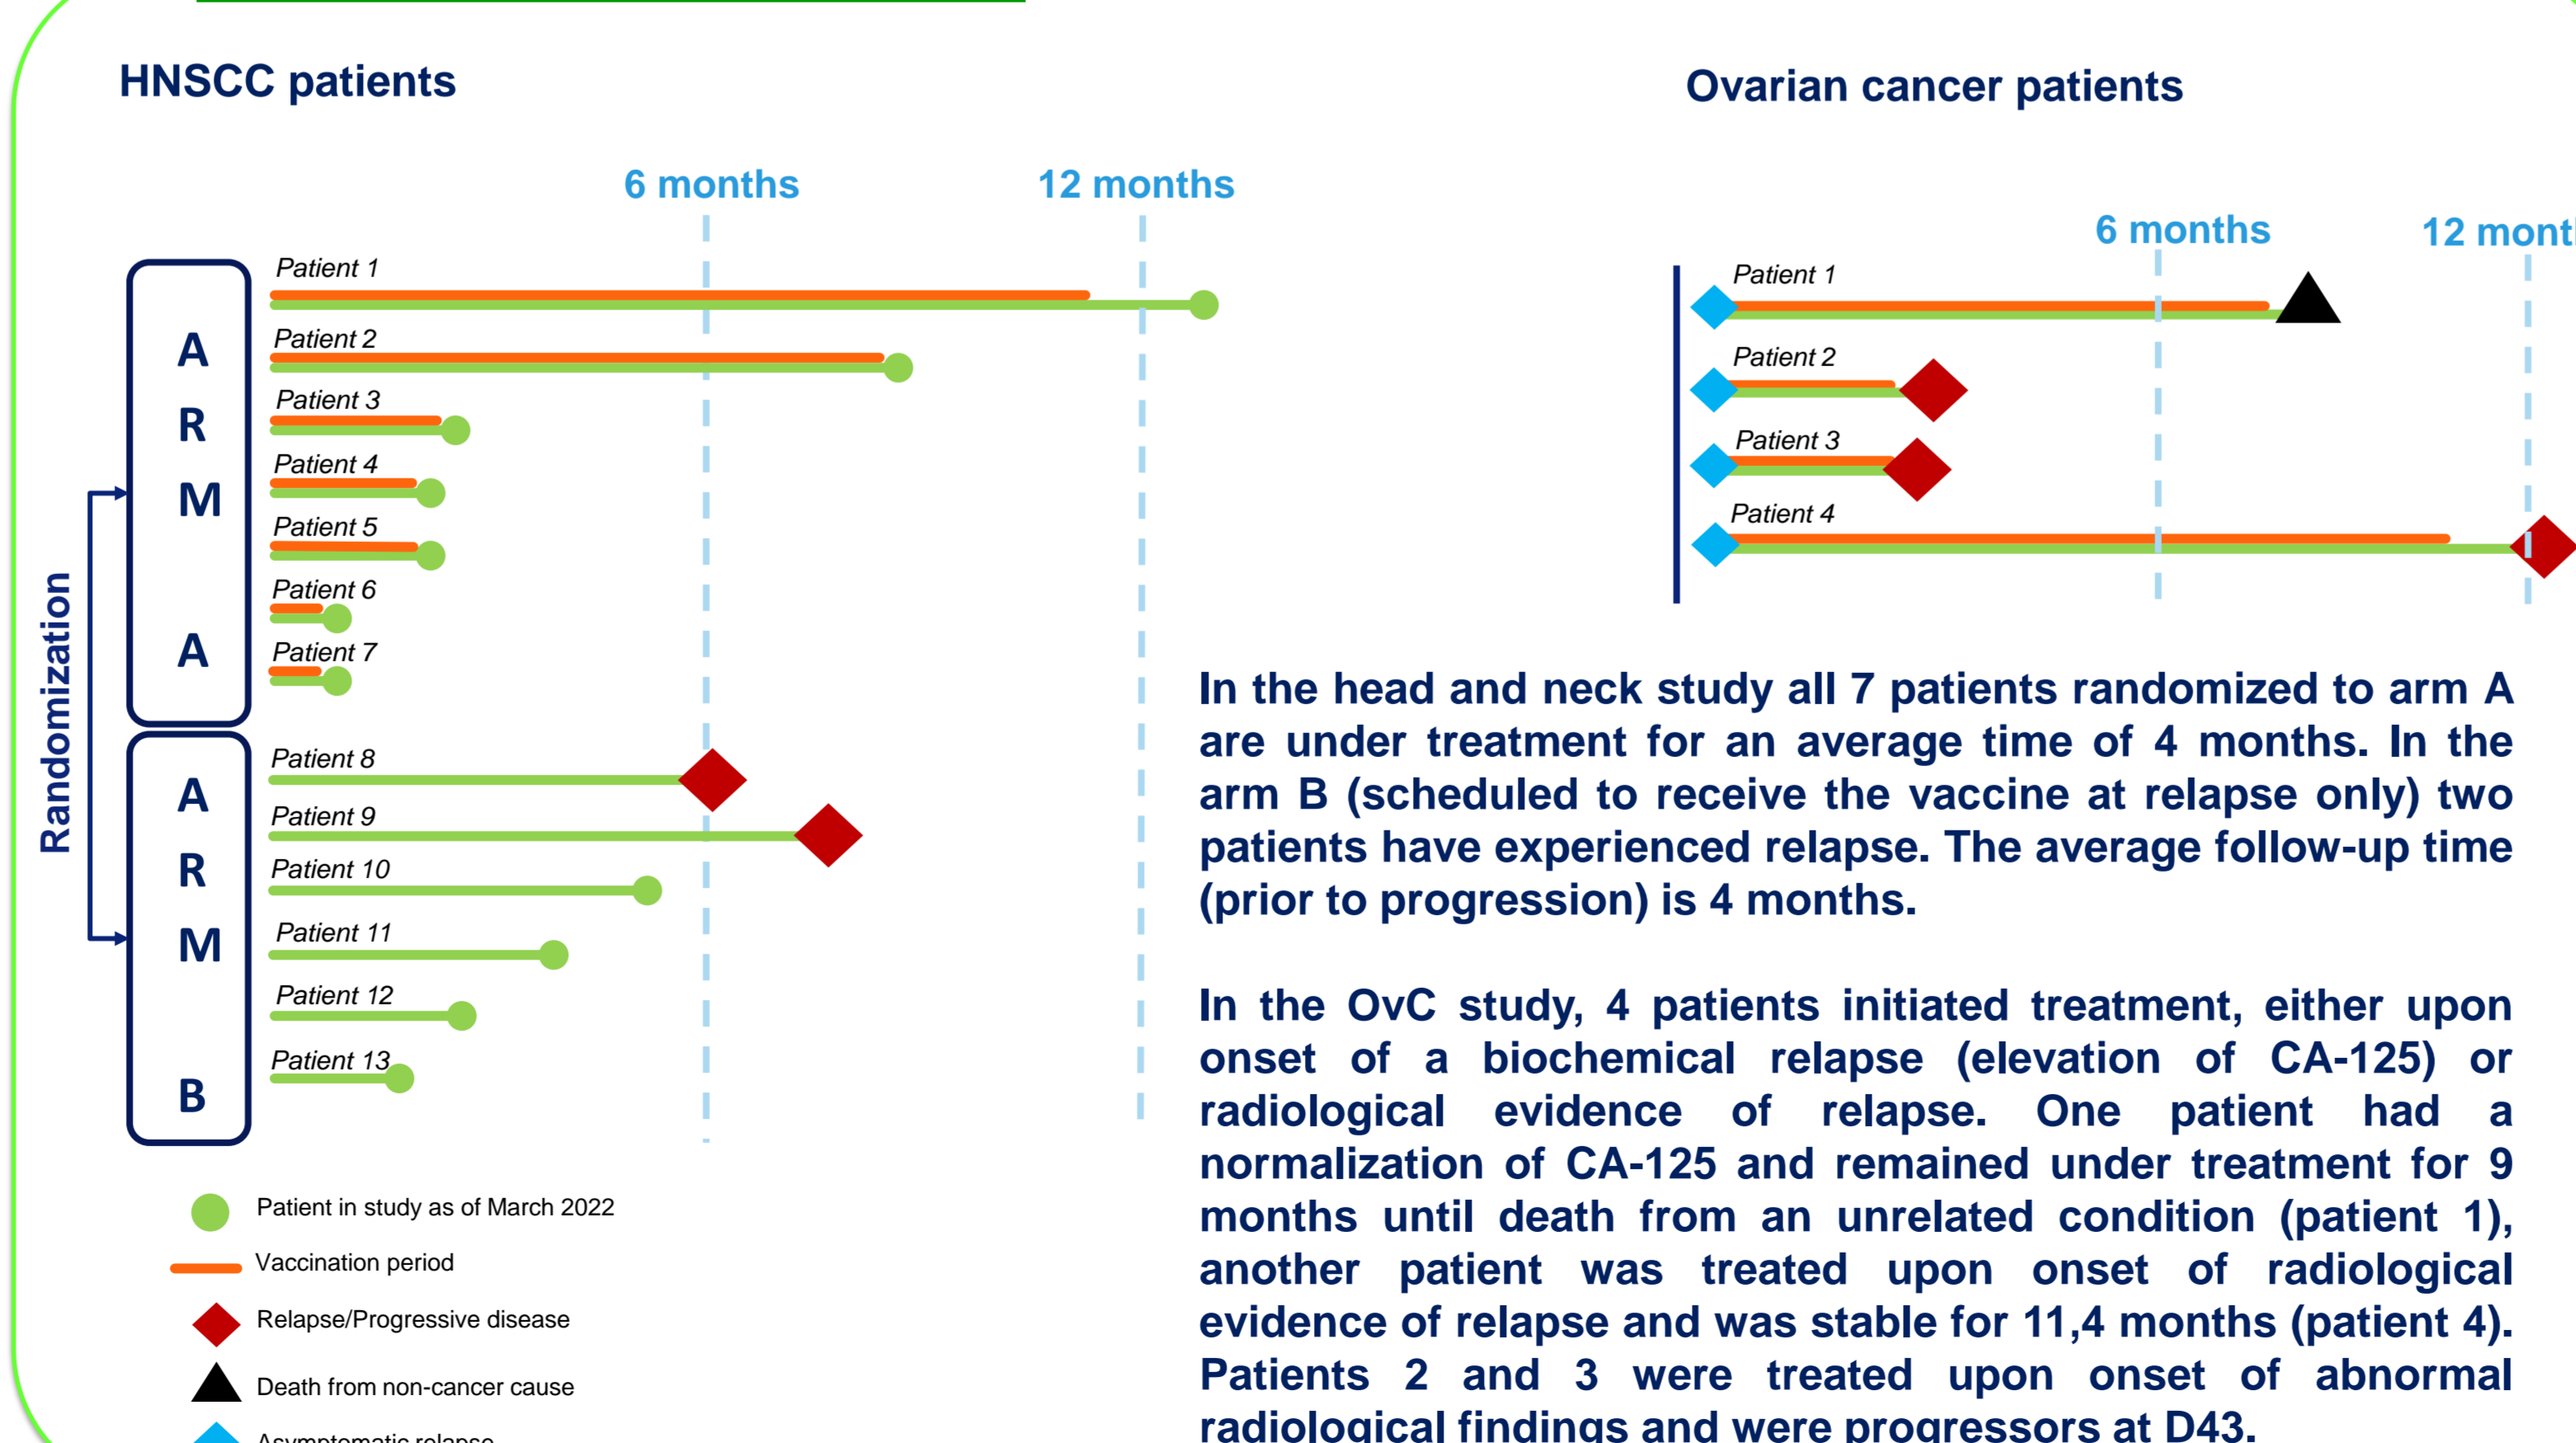

SAFETY FINDINGS

TG4050 was generally well tolerated. All treatment-related AEs were mild or moderate and most of them were injection site reactions. Safety data were available from 10 patients at the time of cut-off.

	Ovarian cancer (N=4)		HNSCC (N=6)		Overall (N=10)	
	N (%)	ev	N (%)	ev	N (%)	ev

CLINICAL FOLLOW-UP

In the head and neck study all 7 patients randomized to arm A are under treatment for an average time of 4 months. In the arm B (scheduled to receive the vaccine at relapse only) two patients have experienced relapse. The average follow-up time (prior to progression) is 4 months.

In the OvC study, 4 patients initiated treatment, either upon onset of a biochemical relapse (elevation of CA-125) or radiological evidence of relapse. One patient had a normalization of CA-125 and remained under treatment for 9 months until death from an unrelated condition (patient 1), another patient was treated upon onset of radiological evidence of relapse and was stable for 11,4 months (patient 4). Patients 2 and 3 were treated upon onset of abnormal radiological findings and were progressors at D43.

ACKNOWLEDGEMENTS

The authors wish to thank all patients, families, caregivers and all technical staff involved in the project.

CONCLUSIONS

The viral vectored personalized vaccine approach was feasible: relevant targets could be identified in all patients, and time of manufacturing and drug release was compatible with the clinical course of treatment. Administration of the vaccine was safe and induced tumor specific T cell response against multiple targets. Early signs of clinical activity are encouraging with changes of tumor markers observed in a treated patient under vaccine monotherapy.
